

Dear editor,

We thank you again for the good suggestions and terminology corrections. Please see our reply below.

Associate Editor Decision: Publish subject to minor revisions (further review by editor) (17 Nov 2020) by Axel Gerdes

Comments to the Author:

Dear Perach Nurial et al.,

many thanks for sending the revised ms. The modifications you did are in line with the reviewers suggestions...

However, there is one thing which gets more confusing through the changes. It is the distinction between single and multi-collector ICPMS ... as you aim to discuss the point that ASH15 appears not to be a suitable RM for single-collector but for MC-ICP-MS... (section 4.5)

What is the basis of it? You mentioned before acquired single- and multi-collector data on ASH-15 in different labs and showed this in a figure, but not discussed differences of the data sets. Perhaps you can do it or don't want to do?

However, other labs acquired reasonable single collector ASH15 data: Frankfurt lab published various papers (e.g. Scardia et al. 2019 QSR, Cruset et al. 2020 J Geol Soc London, and Marine Petrol Geol 120) in which we used ASH15 and yielded precise ages (+-2%), within the uncertainty of the published ASH15 data. The same applies to Guillong et al. 2020 (this Spec. volume) ... within 2% (excess of variance). At least there is currently no proof that LA MC-ICPMS data is much better than LA SC-ICPMS data.

It becomes a bit more confusing the section 4.5. The text partly speaks of sector-field ICPMS instead of MC-ICPMS, elsewhere it seems that Sectorfeld = MC-ICPMS is used, and for single-collectors "including Q-ICPMS" is added. It seems that the authors did not want to commit themselves or have made some changes based on the reviewer's comments, but not applied this consistent throughout the text. So the unexperient reader still gets the impression that compared with MC-ICPMS, single collector is not suitable for ASH15 analyses. While experient reader might come to the conclusion that the authors are confused and want to make a statement towards MC-ICPMS..

The main controlling factor is simply sensitivity or better signal strength (=depending on concentration and spot size and instruments sensitivity). Sector-field (single- and multi-collector !!!) are more sensitive than quadropole ICP-MS.

Multicollector ICPMS are usually more sensitive than single-collector SF-ICPMS. However, if you consider older generation of MC-ICPMS and the MC-ICPMS from one company compared to that from another company (Neptune higher sensitivity than Nu Plasma; Element XR > Attom) , it stays true only in relative terms. The same applies to the older Element2 versus the ElementXR with Jet-interface.

So I would suggest that you change the text in section 4.5, and use instead a term like (line 424) less-sensitive ICP-MS (e.g. most quadropole ICP-MS) and more-sensitive ICPMS (e.g. new generation of single and multi-collector ICPMS) for text line 427. And "Finally the JT can be used for most single- and multi-collector sector-field ICPMS instrument as well as the newer generation of quadropole ICPMS.

Answer: we apologies for the confusing terminology and we have changed it as suggested to 'less-sensitive ICP-MS (e.g. most quadropole ICP-MS)' and 'more-sensitive ICPMS (e.g. new generation of single and multi-collector ICPMS)'

- Please check the text again for typos/spelling, I found 3 times "available" (line 288, 307, 319). Avilable

Thanks, corrected!

- Fig 4b (BGC) What stands this for BGS? Please change and explain it in the text.

Corrected to BGS for 'British Geological Survey' and also also explained in figure caption.

- Line 330 primary MS ??? you mean primary RM

Corrected to RM (reference material)

- you consistent single-collector and multi-collector... in the text you write as well single collector ICP

Thanks, we have changed to single-collector and multi-collector throughout the text

Best wishes Axel Gerdes

17 **Abstract**

18 Latest advances in laser ablation inductively coupled plasma mass spectrometer (LA-ICPMS)
19 allow for accurate *in-situ* U-Pb dating of carbonate material, with final age uncertainties usually
20 >3% 2 σ . Cross-laboratory reference materials (RMs) used for sample-bracketing are currently
21 limited to WC1 calcite with an age of 254.4 ± 6.5 (2 σ). The minimum uncertainty on any age
22 determination with the LA-ICPMS method is therefore $\geq 2.5\%$, and validation by secondary
23 RMs ~~are~~is usually performed on in-house standards. This contribution present a new reference
24 material, ASH-15, a flowstone that is dated here by isotope dilution (ID) TIMS analysis
25 using ~~36-37~~ sub-samples, 1-7 mg each. Age results presented here are slightly younger

26 compared to previous ID-IRMS U-Pb ~~dating dates~~ of ASH-15, but within uncertainties and in
27 agreement with *in-situ* analyses (using WC1 as the primary RM). We provide new correction
28 parameters to be used as primary or secondary standardization. The suggested $^{238}\text{U}/^{206}\text{Pb}$
29 apparent age, not corrected for disequilibrium and without common-lead anchoring, is $2.965 \pm$
30 0.011 Ma (uncertainties are 95% confidence intervals~~2 σ~~). The new results could improve the
31 propagated uncertainties on the final age with a minimal value of 0.4%, which is approaching
32 the uncertainty of typical ID analysis on higher-U materials, for example, such as zircon (~~<1%~~
33 ~~2 σ~~). We show that although LA-ICPMS spot analyses of ASH-15 exhibits significant scatter in
34 their isotopic ratios, the down-hole fractionation of ASH-15 is similar to that of other reference
35 materials. This high-U (~1 ppm) and low Pb (<0.01 ppm) calcite is most appropriate as a
36 reference material for other speleothem-type carbonates but requires more-sensitive ICP-MS
37 instruments such as the new generation of single-collector and multi-collector ICP-MS
38 sensitive sector field ICP-MS instruments. Reference materials with high Pb and low U or both low U
39 and Pb compositions are still needed to fully cover the compositional range of carbonate
40 material but may introduce analytical challenges. ~~For LA work, we recommend the use of the~~
41 ~~new ID-TIMS ages that are 1.3–1.5% younger than previously suggested, because of the lower~~
42 ~~uncertainties (0.4%), the large number of sub-samples (n=36), the use of the EARTHTIME~~
43 ~~isotopic tracers, and the small aliquots (1–7 mg) that are more representative of laser ablation~~
44 ~~spot analysis.~~

45

46 **Introduction**

47 Recent advances in laser ablation techniques applied to multi-phase carbonates allow for
48 accurate dating of a variety of sample types, including calcite cements (Li et al., 2014; Godeau
49 et al., 2018; Anjiang et al., 2019; Holdsworth et al., 2019), hydrothermal veins (Coogan et al.,

50 2016; MacDonald et al., 2019; Piccione et al., 2019), fault-related veins, breccia cement, and
51 slickenfibers (Ring and Gerdes, 2016; Roberts and Walker, 2016; Goodfellow et al., 2017;
52 Nuriel et al., 2017; Hansman et al., 2018; Parrish et al., 2018; Nuriel et al., 2019), and
53 speleothems (Woodhead and Petrus, 2019). With increasing attention ~~on~~to climatic, seismic,
54 and environmental events in the geological record, there is a growing need for dating
55 techniques that can be accurately and easily implemented ~~to~~for samples at the sub-millimeter
56 scale. This newly emerging technique has the potential to contribute to our understanding of
57 the duration, rate, and extent of these important events in the geological record.

58 The *in-situ* approach has a great research potential for studying texturally complex samples
59 because it can resolve problems of age mixing of different phases or averaging of continuous
60 growth at the sub-millimeter scale, and thus increase the overall accuracy of the dated material.
61 While the precision of traditional isotope-dilution (ID) U-Pb analyses is still favorable (<1%
62 2σ) (Woodhead and Petrus, 2019), the increasing analytical development of the LA-ICPMS
63 method indicates the potential for improving the currently reported uncertainties (usually >3%
64 2σ). Finding the right matrix-matched reference material (RM) is a major hurdle for LA
65 analyses of carbonates because of the variety of mineralogy (calcite, dolomite, and aragonite),
66 textures, composition (e.g. high-magnesium calcite, high common-lead), and ages (e.g. low
67 radiogenic lead in young samples). Textural differences such as microcrystalline, fine- and
68 coarse-grained material, between the unknown and RMs can contribute to high uncertainties
69 due to differences in ablation efficiency, down-hole fractionation, and differences in crater
70 morphology (e.g. Guillong et al., 2020 and Elisha et al, 2020, this issue). Observed deviations
71 are potentially up to 20% of the final intercept age depending on the degree of crater geometry
72 mismatch and are related ~~to~~ either to downhole fractionation and/or matrix effects (Guillong
73 et al., 2020).

74 Currently, the most commonly used procedure for mass-bias correction in the LA method, is
75 by standard-sample bracketing. For this, the $^{238}\text{U}/^{206}\text{Pb}$ LA-age of the RMs is corrected to the
76 true RM's $^{238}\text{U}/^{206}\text{Pb}$ apparent age (not corrected for disequilibrium) as measured
77 independently by an ID-IRMS method (~~e.g.~~ ID-TIMS or ID-MC-ICPMS). The RMs are
78 measured throughout each session along with the unknown samples, and a normalization factor
79 is applied to correct both the RMs and the unknowns. Uncertainty propagation onto the age of
80 the unknowns includes the uncertainties of the 'true' RM age. As a result, the accuracy of the
81 LA analyses can only be as good as the uncertainties on the age of the RMs which is by itself
82 subjected to analytical challenges due to natural heterogeneities, impurities, and textural
83 complexities at the sub-millimetre scale. It is therefore essential that the 'true age' of the
84 reference material will reflect these complexities while maintaining minimal uncertainties.

85 Currently, several in-house standards are being used as reference materials, including Duff
86 Brown Tank (64 Ma; Hill et al., 2016), and JT (13.797 ± 0.031 Ma; Guillong et al., 2020). The
87 only well-characterized reference material that is distributed across laboratories is the WC1
88 calcite with an age of 254.4 ± 6.5 ~~2 σ s~~ (2.5%) (Roberts et al., 2017). The use of WC1 alone for
89 mass-bias correction has several disadvantages. First, it is highly recommended with all in situ
90 U-Th-Pb geochronology to use secondary RMs to validate any correction parameters that are
91 being used, and to appropriately propagate uncertainties. Second, the relatively high
92 uncertainty (2.5%) on the age of WC1 sets a minimal uncertainty on any LA U-Pb age
93 determination. Finally, the quantity of the WC1 sample that is currently available for future
94 work is limited and is likely to not fully meet the growing demands of the LA scientific
95 community; although, we note here that there is a potential for further sample collection from
96 the original site.

97 This contribution introduces a new carbonate reference material that can be widely used for *in-*
98 *situ* dating of calcite as primary or as cross-reference material with other available standards.

99 We characterise the reference material at various resolutions using a combination of (1) laser
100 ablation imaging (20 µm square beam); (2) LA spot analysis, ~80-110 µm in diameter,
101 conducted on both single-collector and multi-collector (MC) ~~and single-collector~~ inductively
102 coupled plasma mass spectrometer (ICP-MS); and (3) ID-TIMS analyses of ~~36-37~~ sub-samples
103 (~1-7 mg aliquots). We discuss several key issues related to the use of ASH-15 sample as a
104 RM, including down-hole fractionation, heterogeneities, and previous bulk analyses, ~~and the~~
105 ~~possible effect of samples size and blank corrections~~, to provide the best correction parameters
106 and suggested protocols for users of the LA scientific community.

107 **1 The ASH-15 flowstone**

108 The ASH-15 flowstone was found in Ashalim Cave, a karstic cave in the central Negev Desert
109 (30°56'36.2" N, 34°44'22.5" E), southern Israel, which is part of the northern margin of the
110 Saharan–Arabian desert belt. The cave entrance is located at an elevation of 414 m above sea
111 level and 67 km SE from the Mediterranean Sea coast. The cave is a three-dimensional
112 hypogene maze with a total length of 540 m, situated in Turonian limestone rock strata, at
113 depths of 0-31 m below the surface. The cave is richly decorated with vadose speleothems,
114 such as stalagmites, stalactites and flowstone, which are not active today because of the aridity
115 of the climate in the area (Vaks et al, 2010, 2018), but periods of their deposition correspond
116 to past episodes of wet climate in present-day desert. The thickness of the speleothems varies
117 from several cm to a few tens of cm. The soil above the cave is silicate loess, originated mainly
118 from aeolian dust (Crouvi et al., 2010) and the present day vegetation is composed of sparse
119 xeric shrubs with <10% vegetation cover.

120 The vadose speleothems of Ashalim Cave are composed of low-Mg calcite, and are divided
121 into a relatively thick Pliocene Basal layer, and thinner Pleistocene layers above it. The Basal
122 layer varies from 5 to 25 cm in thickness and comprises c. 90% of the speleothem volume in

123 the cave. It is composed of massive yellow calcite crystals (Fig. 1a-b), often showing
124 continuous growth in stalagmites and flowstone, suggesting deposition from continuously
125 dripping water. In all speleothems the Basal layer is terminated at its top by a <1 mm layer of
126 microcrystalline calcite, evaporite minerals and reddish clays (Fig. 1a), that is interpreted as a
127 hiatus (growth break) separating the Basal Pliocene layer and Quaternary layers above it (Vaks
128 et al., 2013). The thickness of Pleistocene top layers varies from several mm to 17 cm, but
129 usually does not exceed a few cm, comprising about 10% of the speleothem volume in the cave.
130 It is composed of alternating layers of brown calcite, with the youngest top layer (where found)
131 composed of yellow calcite. Several variably colored layers <1 mm thick of microcrystalline
132 calcite, evaporite minerals and reddish clays are found within the columnar crystalline structure,
133 suggesting hiatuses in speleothem deposition (Vaks et al., 2013).

134 The youngest periods of speleothem deposition in several Ashalim Cave speleothems were
135 dated by the ^{238}U - ^{230}Th method and occurred from 221 ka to 190 ka and from 134 to 114 ka
136 (Vaks et al, 2010). Earlier periods of deposition were dated by the U-Pb method on ASH-15
137 flowstone ~~and are dated to at~~ 1.272 ± 0.018 Ma (ASH-15-C), and the Basal layer of ASH-15
138 flowstone (layers D-K) ~~dated to at~~ c. ~3.1 Ma (Fig 1a). These layers have been dated in three
139 different labs following several protocols for ID analysis (Vaks et al., 2013; Mason et al., 2013).
140 The U concentrations in speleothem calcite range between 1.9 and 19.7 $\mu\text{g/g}$ and the amounts
141 of non-radiogenic Th are negligible (Vaks et al., 2010).

142

143 **Figure 1.** Sample ASH-15 from Ashalim Cave. (a) ~5 kg block of sample ASH-15 flowstone
 144 consisting of the massive Pliocene yellow Basal layer (>2 cm calcite crystals; section D–K)
 145 and the brown Quaternary layer (top section, A–C), the thin layer between the two stratigraphic
 146 members represents a growth break (hiatus). The main U-Pb ages of Vaks et al., 2013 are
 147 indicated: (b) In-situ flowstone within Ashalim Cave from which ASH-15 was sampled,
 148 showing the large reservoir of this flowstone.

149

150 2 Sample ASH-15 textural characterization

151 The ASH-15 thin-section includes section D and E ~~of the ASH-15 sample~~ (see location in
 152 Fig.1a). Overall the thin-section examination indicates that the original texture is preserved
 153 with consistent growth direction, no observed hiatus, and no indications for dissolution and
 154 recrystallization. A spot analysis array, 85 μm in diameter, targeted along growth ~~bands-zone~~
 155 and ~~perpendicular to along~~ -growth ~~direction are-is~~ visible in Fig. 2a-c. The ASH-15 sample
 156 shows no luminescence under cathodoluminescence light (Fig. 2c), suggesting formation under
 157 oxidising conditions. The slight bright luminescence observed within grain boundaries,
 158 discontinuities, and veins (arrows in Fig. 2b-c) may suggest ~~for~~ the presence of fluid inclusions,
 159 textural differences, or some local replacement within these areas. These areas should be

160 avoided if possible during spot analysis. The relatively homogenous low luminescence may
 161 suggest for a single-phase continuous calcite growth, whereby precipitation occurred relatively
 162 rapid from the same fluid source (e.g. with consistent Mn^{2+} Fe^{2+} composition) and/or under
 163 similar precipitation redox conditions. This 15 cm thick, ~3 Ma Pliocene layer (section D-K)
 164 is essentially of the same age. For this reason, previous dating of this sample also considered a
 165 similar initial $^{234}U/^{238}U$ activity ratio for disequilibrium correction (Mason et al., 2013; Vaks
 166 et al., 2013). The ASH-15 reference material consists of the whole Pliocene section that
 167 terminates with a sharp transition to the darker Pleistocene layers above it (section A-C; see
 168 Fig. 1b). About 3 kg of ASH-15 sample are excavated from the Ashalim Cave (Fig. 1a), and
 169 potentially much more can be sampled in the future (we estimate more than 10 kg of sample;
 170 Fig. 1b). The ASH-15 flowstone is therefore a good candidate for a reference material because
 171 of its large volume, high U concentrations, and potentially homogenous age which will be
 172 examine next.

173

174 **Figure 2.** ASH-15D-E thin-section. (a) cross-polarized (XPL) scan of ASH-15D-E thin-section,
 175 36 mm long, showing continuous growth (no hiatus), and consistent growth direction (indicated
 176 with yellow arrow). Spot analyses are targeted either sub-parallel to growth band-zone or
 177 perpendicular-sub-parallel to growth direction; (b) close-up on spot array analyses (location is

178 shown in a) with 85 μm diameter; (c) CL image ~~of the same area~~ showing no luminescence
179 ~~and except for~~ some bright luminescence within grains boundaries and veins (arrows).

180 3 Methods

181 3.1 Elemental mapping

182 The sample ASH-15 was cut perpendicular to the growth ~~bands-zone~~ of section D and E (see
183 Fig. 1b) in order to examine heterogeneities across growth ~~bands-zone~~ and within. Thin-sections
184 were then examined under plane- and cross-polarized light (XPL/PPL), and
185 cathodoluminescence (CL) microscopy (Fig. 2). The central part of the thin-section was also
186 analyzed for elemental distribution of selected elements. The elemental maps were measured
187 via LA-ICPMS, carried out on a 193 nm ArF excimer laser ablation system (Analyte G2
188 Teledyne Photon Machines Inc., Bozeman MT) coupled to an ICP-QMS (Agilent 7900, Agilent
189 Technologies, Santa Clara CA). The laser was equipped with a Photon Machines HeEx II
190 ablation chamber and an Aerosol Rapid Introduction System (ARIS). The experiments were
191 carried out using acquisition parameters (both on the ICP and on the laser) modelled using the
192 approach of van Elteren et al (2019; 2018) to avoid artefacts (e.g., aliasing, smear, blur). All
193 images (500x500 pixels) were acquired using a 20 μm square beam, fluence of 3.5 Jcm^{-2} , 294
194 Hz repetition rate and dosage of 10 (~~10 overlapping pulses per spot size which~~ amounting to a
195 scanning speed of 588 μms^{-1}). The masses monitored were ~~^{24}Mg , ^{55}Mn , ^{63}Cu , ^{85}Rb~~ ^{88}Sr , ^{137}Ba ,
196 ^{206}Pb , ^{208}Pb , ^{232}Th , and ^{238}U and the images were constructed using Photon Machines' HDIP
197 data reduction software (van Malderen, 2017).

198 3.2 LA-MC-ICPMS spot analyses

199 A thin section of ASH-15 was dated by U-Pb laser ablation multi-collector inductively coupled
200 plasma mass spectrometry (LA-MC-ICPMS) following the method described in Nuriel et al.
201 (2017). A Nu Plasma 3D was employed in conjunction with a Photon Machines Excite 193nm

202 Excimer laser equipped with a HelEex two volume cell. The laser was fired for 15 s during
203 analysis, using a ~~repetition~~ rate of 10 Hz, a spot size of 85 μm , and a fluence of approx. 1
204 J/cm^2 . The Nu Plasma 3D allows for the simultaneous acquisition of ^{238}U , ^{235}U , ^{232}Th , ^{208}Pb ,
205 ^{207}Pb , ^{206}Pb , $^{204}\text{Pb}(+\text{Hg})$, and ^{202}Hg , where ^{238}U - ^{232}Th are measured on Faraday detectors and
206 the low-side masses are measured on Daly detectors. Instrumental mass-bias was corrected
207 using a two-step approach: both the $^{207}\text{Pb}/^{206}\text{Pb}$ and $^{206}\text{Pb}/^{238}\text{U}$ ratios were first corrected to
208 NIST-614 glass reference material in *Iolite 3* using the geochronology reduction scheme (Paton
209 et al., 2010) to account for both mass-bias ($^{207}\text{Pb}/^{206}\text{Pb}$) and instrumental drift ($^{207}\text{Pb}/^{206}\text{Pb}$ and
210 $^{206}\text{Pb}/^{238}\text{U}$). The Tera-Wasserburg data, output from *Iolite*, was then plotted and $^{206}\text{Pb}/^{238}\text{U}$
211 ratios of all RMs and unknowns were adjusted such that the primary calcite reference
212 material—WC-1—yielded an age of 254 Ma (Roberts et al., 2017). This resulted in accurate
213 dates for both our secondary calcite RM; Duff Brown Tank at -66.8 ± 3.4 Ma (previously
214 reported 64 Ma; Hill et al., 2016) and a $^{207}\text{Pb}/^{206}\text{Pb}$ date of zircon RM at 566.0 ± 2.8 Ma
215 (previously reported Sri Lanka, 564 Ma; Gehrels et al., 2008), of 66.8 ± 3.4 Ma and a $^{207}\text{Pb}/^{206}\text{Pb}$
216 date of a 566.0 ± 2.8 Ma. Uncertainty propagation of individual ratios was assessed by
217 reproducibility of the NIST614 and SL RMs (n=44 in both cases) and added in quadrature such
218 that the MSWD of each weighted average is ≤ 1 and that the uncertainty is no better than 2%
219 (long-term reproducibility); this resulted in propagated uncertainties of 2.5% and 2% for the
220 $^{206}\text{Pb}/^{238}\text{U}$ and $^{207}\text{Pb}/^{206}\text{Pb}$ ratios, respectively. Given that the typical uncertainties of the
221 $^{206}\text{Pb}/^{238}\text{U}$ and $^{207}\text{Pb}/^{206}\text{Pb}$ ratios of the unknowns was $>10\%$ and $>3\%$, respectively, the
222 uncertainty propagation on individual ratios had little effect on the calculation of the final date
223 of ASH-15. The thin section of ASH-15 was measured both parallel to the length of section
224 (303 spots, and perpendicular to it (101 spots). Data are plotted using Isoplot (Ludwig, 1998).

225

226

227 3.3 LA-ICPMS spot analyses

228 Analyses were conducted at the Geochronology and Tracers Facility, British Geological
229 Survey (Nottingham, UK). The instrumentation comprised a New Wave Research 193UC
230 excimer laser ablation system fitted with a TV2 cell, coupled to a Nu Instruments Attom single
231 collector ~~inductively coupled plasma mass spectrometer (ICP-MS)~~. The method follows the
232 protocols described in Roberts and Walker (2016) and Roberts et al. (2017). Laser parameters
233 varied slightly per session, but typically involve a pre-ablation cleaning spot of 150 μm , fired
234 at 10 Hz with a fluence of $\sim 6 \text{ J/cm}^2$ for 2 seconds, and ablation conditions of 80-100 μm spots,
235 fired at 10 Hz with a fluence of $\sim 6-8 \text{ J/cm}^2$ for 25-30 seconds. A 60 second background is taken
236 before every set of standard-bracketed analyses, and a 5 second washout is left between each
237 ablation. Normalization of Pb-Pb ratios is achieved using NIST614 glass (values of Woodhead
238 and Hergt, 2001), and WC-1 carbonate for Pb-U ratios (Roberts et al., 2017). Data reduction
239 uses the Time Resolved Analysis function of the Nu Instruments Attolab software, and an excel
240 spreadsheet, with uncertainty propagation following the recommendations of Horstwood et al.
241 (2016).

242

243 3.4 ID-TIMS U-Pb geochronology

244 Isotope dilution thermal ionization mass spectrometry (ID-TIMS) U-Pb geochronology was
245 performed at the Institute of Geochemistry and Petrology of ETH Zurich (ETHZ) and at the
246 Department of Earth Sciences of the University of Geneva (UNIGE). ~~Millimeter~~Millimetre-
247 sized chips of the ASH-15-D and ASH-15-K calcite were extracted using stainless steel tools.
248 Larger chips were further sub-divided resulting in $\sim 1-7 \text{ mg}$ aliquots. Individual chips were
249 transferred into 3 ml Savillex beakers and repeatedly ultrasonically cleaned in ultrapure acetone
250 and water. Cleaned sampled were transferred into pre-cleaned 3 ml Savillex beakers, spiked

251 with ~5-10 mg EARTHTIME (^{202}Pb -) ^{205}Pb - ^{233}U - ^{235}U tracer solution (Condon et al., 2015) and
252 dissolved in 6N HCl at 120°C on a hotplate for ~30 minutes to assure complete dissolution and
253 sample-spike equilibration. Dissolved samples were dried down and redissolved in 1N HBr.
254 Uranium and Pb were separated using a single-column (50 μl , AG1-X8 resin) HBr-HCl anion
255 exchange chemistry. The Pb fraction was dried down with a drop of H_3PO_4 after a single
256 column pass. Uranium was dried down, redissolved in 3N HCl and further purified with a HCl-
257 based second column pass before drying it down with a drop of H_3PO_4 . Uranium and Pb were
258 loaded on outgassed single Re filaments with ~1 μl of Si-gel emitter for thermal ionization
259 mass spectrometry. Uranium and Pb isotope ratios were measured on a Thermo TRITON Plus
260 at ETHZ and a Thermo TRITON at UNIGE. Lead isotopes were measured on the axial
261 secondary electron multiplier employing dynamic peak-hopping routine collecting masses
262 (202), 204, 205, 206, 207 and 208. Measured Pb isotope ratios were corrected for mass
263 fractionation either using the double spike (ETHZ) or using a mass fractionation factor of 0.15
264 \pm 0.03 %/amu for single Pb spiked samples (UNIGE). Uranium isotope ratios were measured
265 as uranium-oxide (UO_2) employing a static measurement routine with Faraday cups connected
266 to amplifiers with 10^{13} ohm feedback resistors (von Quadt et al., 2016; Wotzlaw et al., 2017).
267 Isotope ratios were corrected for isobaric interferences from minor UO_2 isotopologues
268 (Wotzlaw et al., 2017) and for mass fractionation using the double spike assuming a $^{238}\text{U}/^{235}\text{U}$
269 ratio of 137.818 ± 0.045 (Hiess et al., 2012) for sample and blank. Total procedural Pb blanks
270 for the HBr-based chemistry at ETHZ are consistently between 0.2 and 0.4 pg. We therefore
271 attribute up to 0.4 pg to laboratory blank with the remaining common Pb being attributed to
272 initial common Pb. Total procedural blanks measured at UNIGE yielded an average of 1.15 pg
273 that was taken as the laboratory blank contribution. Data reduction and uncertainty propagation
274 was performed using Tripoli and an Microsoft Excel-based spreadsheet that uses the algorithms
275 of Schmitz and Schoene (2007). Isochron calculations were performed using IsoplotR

276 (Vermeesch, 2018). All uncertainties are reported at 95% confidence ignoring systematic
277 uncertainties associated with the tracer calibration and decay constants unless otherwise stated.

278 **4 Results**

279 All analyses were performed on ASH-15-D-K yellow Pliocene layer, abbreviated here as
280 “ASH-15” unless specification of ASH-15-D, E etc. is indicated. The ASH-15-A-C brown
281 Pleistocene layer is not part of the ASH-15 suggested reference material.

282 **4.1 LA elemental mapping**

283 Elemental mapping for ^{88}Sr , ^{137}Ba , ^{206}Pb , ^{208}Pb , ^{238}U and $^{238}\text{U}/^{206}\text{Pb}$ ratio shows that the
284 distribution of most elements is relatively homogeneous (Fig.3), and in good accordance with
285 the luminescence data. Higher intensities for ^{238}U and ^{88}Sr were observed along grain
286 boundaries and discontinuities, whereas Pb and the rest of the trace elements are more
287 homogeneously distributed, arguing for steady environmental conditions ~~that have kept steady~~
288 during the deposition. Ten random regions of interest (ROI) were selected throughout the
289 sample to mimic 10 spot analysis carried out at 85-90 microns spot size – just like one would
290 do for U-Pb geochronology, ~~for example~~. These ROIs were generated by drawing on the map
291 circular regions with the radius of 85 or 90 microns in diameter. The pixels comprising each
292 ROI were pooled together as representing the equivalent of a single spot analysis. The statistical
293 data for each cluster (data are given in supplementary file) ~~was-were~~ compared. The average
294 values for all pixel data ~~is-are~~ within 2 standard errors and in good agreement, indicating that,
295 at least based on the elemental distribution we measured, the sample is relatively homogeneous
296 for a natural sample. To further investigate the chemical homogeneity of the sample, a random
297 transect through one of the growth zones was drawn and the signal intensities for ^{238}U were
298 extracted. The transect data also indicate that ^{238}U variations are within 2 standard errors of the
299 average value. (full data is available in Table S1 in the supplement).

300

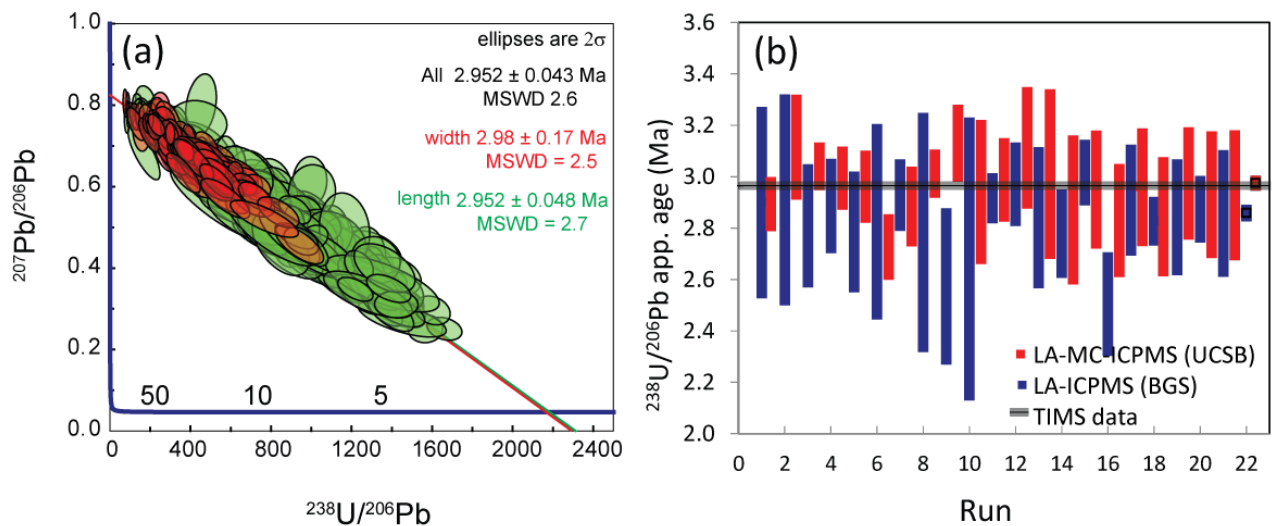

301 **Figure 3.** Signal intensity maps of ASH-15. For $^{238}\text{U}/^{206}\text{Pb}$, ^{88}Sr , ^{137}Ba , ^{206}Pb , ^{208}Pb , and ^{238}U
 302 (a-d). The plotted signal was corrected for blank and analytical drift of the instrumentation.
 303 Note that each distribution map has its own signal intensity scale. The position of the regions
 304 of interest and transect is shown in (a). The circles designating the location of the regions of
 305 interest are not at scale- [\(data is available in Table S1 in the supplement\)](#).

306 4.2 LA-MC-ICPMS spot analyses

307 Data and calculated ages for the LA-MC-ICPMS transects are shown in Tera-Wasserburg
 308 space in Fig. 4 (n = 379 of 412 total spots). Analyses rejected from the age calculation include
 309 those with $^{207}\text{Pb}/^{206}\text{Pb}$ uncertainties larger than 0.1% (n = 2) and those with high common-Pb
 310 contents (^{208}Pb cps >5000; n = 17). A further 14 spots plotted below the array; these data were
 311 [represent](#) the first 1–2 mm of spots of the lengthwise transect (lower right in Fig. 2a), and
 312 suggest that a small percent of ASH-15 may behave differently during ablation and/or may
 313 have been subsequently modified after crystallization; upon inspection, this portion of the
 314 section contains more pore space and impurities than the majority of the section. The remaining

315 379 define a normally distributed array with a lower intercept age of 2.952 ± 0.043 Ma (MSWD
316 = 2.5), which is well within uncertainty of the new ID-TIMS data presented ~~herein~~ (full data is
317 available in Table S2 in the supplement) ~~and the scatter observed in the LA data (i.e., MSWD~~
318 ~~≥ 1) is lower compared with scatter observed in the ID-TIMS data.~~ The calculated upper
319 intercept of each transect is equivalent and within 1% of the common Pb composition
320 calculated from the ID-TIMS data. Not surprisingly, the lengthwise transect reveals a larger
321 spread in common/radiogenic Pb ratios; this transect crosses more growth zones and has a
322 higher probability of sampling a variety of concentrations of both Pb and U. Conversely, the
323 more limited spread in common/radiogenic Pb ratios appears to reflect the limited sampling of
324 growth zones, and would suggest that individual growth zones contain a relatively limited
325 range of concentrations in U and Pb. The slightly higher MSWD for the lengthwise transect
326 (2.7) relative to the growth zone transect (2.5) could also reflect these inherited compositional
327 differences during growth history, and a resulted “mixing” or “averaging” of different growth
328 phase along calcite continuous growth.

329 Variations of ASH-15 ages during 20 different runs (with 5-30 spot analysis in each) using
330 both ~~single (ICPMS) and single-collector and~~ multi-collector ~~(MC-ICP-MS)~~ are shown in Fig.
331 4b (full data is available in Tables S3-S5 in the supplement). The ages are calculated using
332 IsoplotR, not anchored to 0.8315 specific common-lead, and are not corrected for
333 disequilibrium. Although there is a large scatter in the ages of the different runs the average
334 ages (marked ~~in with black box~~ thick lines) ~~are plotted~~ close to the new ID-TIMS ages, or are
335 slightly younger in age.

336

337 **Figure 4.** LA-MC-ICPMS analyses of calcite ASH-15. (a) Tera-Wasserburg concordia space
 338 plot (n=385) for (n=385). Spots-spots analysis within lengthwise transect (green) and along
 339 growth zone transect (red). Calculated age, 2 σ error and MSWD are given for both and for all
 340 spots together; (full data is available in Table S2 in the supplement); (b) Variations of ASH-15
 341 ages during different runs using both single-collector (at the British Geological Survey) and
 342 multi-collector (at University of California Santa Barbara) ICP-MS. Ages are calculated using
 343 WC1 as primary MSRM; the new ID-TIMS age is indicated with a grey line; (full data is
 344 available in Table S3-S5 in the supplement) ~~Ages are calculated using IsoplotR, anchored to~~
 345 ~~0.8315 common-lead, and are not corrected for disequilibrium.~~

346 4.3 Down-hole fractionation

347 Reference material is important for correction of both laser-induced elemental fractionation
 348 (LIEF) and ~~in~~-plasma-related ionization efficiency. Ideally, the reference material should
 349 resemble the unknown samples as much as possible in terms of its chemistry (e.g. Mg and Fe
 350 content), texture (i.e. micritic, crystalline), and age. The WC1 and ASH15 are both low-Mg
 351 calcite but they are very different in ~~their~~-textures and age. The ASH15 is a ~3 Ma, well-
 352 crystallized elongated calcite (up to 1 cm) and WC1 is a 254 Ma recrystallized botryoidal
 353 calcite, formed after aragonite. Despite these differences, both WC1 and ASH15 display a very

354 similar down-hole fractionation pattern (Fig. 5d). Fig. 5 shows stacked integration plots of the
355 down-hole raw $^{206}\text{Pb}/^{238}\text{U}$ ratio of different RMs including, the ASH15, WC-1, and Duff
356 Brown Tank (Black and Gulson, 1978). The ASH15 displays s much larger scatter in the raw
357 data (Fig. 5a) in comparison to both WC1 and Duff Brown Tank (Fig. 5b-c), however, the
358 average value yielded identical down-hole ~~patterns-fractionation~~ to that of WC-1 (Fig. 5d).
359 Duff Brown Tank is also consistent with the down-hole patterns but less steep in comparison
360 to WC1 and ASH15 (Fig. 5d). This comparison suggests that down-hole fractionation and
361 laser-induced elemental fractionation (LIEF) is-are similar among the different RMs. It is thus
362 suggested that differences in measured and expected $^{206}\text{Pb}/^{238}\text{U}$ ratios ~~between-measured-and~~
363 ~~expected~~-in calcite material are likely to be caused mostly by plasma-ionization differences
364 between unknown samples and RMs.

365

366 **Figure 5.** Stacked integration plots of raw ^{207}Pb -corrected $^{206}\text{Pb}/^{238}\text{U}$ ratios for calcite reference
 367 materials ASH-15, WC-1, and Duff Brown Tank. The low Pb concentration in ASH-15 yields
 368 more scatter, but average slopes of all RMs are similar, with 1-2% change in age over 10
 369 seconds (100 pulses) of ablation. The results suggest ~~for~~ minimal differences in down-hole
 370 fractionation of the different RMs.

371 4.4 ID-TIMS results

372 Twelve aliquots of ASH-15D analyzed at ETHZ yielded $^{238}\text{U}/^{206}\text{Pb}$ ratios between 1096 and
373 2084 and $^{207}\text{Pb}/^{206}\text{Pb}$ ratios between 0.0825 and 0.4403 ([full data is available in Table S6 in the](#)
374 [supplement](#)). Plotted in Tera-Wasserburg space, ~~this~~ ~~these~~ data yields a single isochron with an
375 initial $^{207}\text{Pb}/^{206}\text{Pb}$ of 0.832 ± 0.015 (uncertainties are 95% confidence intervals) and a concordia
376 intercept age of 2.967 ± 0.022 Ma (Fig. 6a). The elevated mean square weighted deviation
377 (MSWD) of 12 is attributed to minor heterogeneities, most likely in the initial $^{207}\text{Pb}/^{206}\text{Pb}$ ratio
378 of the speleothem calcite. Twelve aliquots of ASH-15K ~~analysed~~ ~~analyzed~~ at ETHZ returned
379 $^{238}\text{U}/^{206}\text{Pb}$ ratios between 723 and 2094 and $^{207}\text{Pb}/^{206}\text{Pb}$ ratios between 0.0720 and 0.5677. In
380 Tera-Wasserburg space, eleven out of twelve aliquots define a isochron with an initial
381 $^{207}\text{Pb}/^{206}\text{Pb}$ of 0.8314 ± 0.0040 and a concordia intercept age of 2.964 ± 0.016 Ma (Fig. 6b). A
382 single aliquot (#5.4) plots significantly below the isochron defined by the other aliquots. The
383 elevated MSWD of 34 together with the single outlier suggest some heterogeneities in the
384 initial $^{207}\text{Pb}/^{206}\text{Pb}$ of the ASH-15K calcite. Thirteen aliquots of ASH-15K ~~analysed~~ ~~analyzed~~ at
385 UNIGE (pink color, Fig. 6b) yielded $^{238}\text{U}/^{206}\text{Pb}$ ratios between 433 and 1853 and and
386 $^{207}\text{Pb}/^{206}\text{Pb}$ ratios ranging from 0.1856 to 0.6660. Twelve of the thirteen analyses yield ~~define~~
387 ~~an~~ ~~best-fit~~ ~~isochron~~ ~~isochron~~ ~~line~~ with an initial $^{207}\text{Pb}/^{206}\text{Pb}$ of 0.814 ± 0.019 and a Concordia
388 intercept age of 2.947 ± 0.065 Ma. The elevated MSWD of 36 confirms the minor heterogeneity
389 of the initial $^{207}\text{Pb}/^{206}\text{Pb}$.

390 The excellent agreement between the ASH-15D and ASH-15K datasets ~~suggest~~ ~~indicates~~ that
391 the entire speleothem growth layer between these two growth zones is of equivalent age with
392 minor heterogeneities in the initial $^{207}\text{Pb}/^{206}\text{Pb}$ ratio and justifies combining the data into a
393 single isochron regression. The combined isochron, using 35 of 37 ~~analysed~~ ~~analyzed~~ aliquots,
394 yields an initial $^{207}\text{Pb}/^{206}\text{Pb}$ of 0.8306 ± 0.0033 and a concordia intercept age of 2.965 ± 0.011

395 Ma with a MSWD of 35 (Fig. 6c). We consider the results of the combined ~~isochron~~-regression
396 as the best reference value for using ASH-15 as a primary reference material.

397 The new TIMS data provide the most extended bulk ~~investigation-analyses-work~~ of the ASH-
398 15 sample, with a total of 37 sub-samples that are separated from bottom (K, n=25) to top (D,
399 n=12) ~~sections of the sample~~. The ~~relatively~~-high MSWD of 35 is suggested to reflect true
400 heterogeneities of the dated material, possibly related to impurities that are concentrated within
401 grain boundaries (as suggested by CL and elemental mapping). We re-calculated previously
402 determined isochron ages of Vaks et al. (2013) and Mason et al. (2013; Fig. 7). We obtained
403 concordia intercept ages of 3.0088 ± 0.053 Ma for ASH-15-D (MSWD=11; n=5) and 3.0153
404 ± 0.042 Ma for ASH-15-K (MSWD=14; n=5) of Vaks et al. (2013) and 3.0015 ± 0.029 for
405 ASH-15-D (MSWD=2; n=5) of Mason et al. (2013). These ages ~~are systematically older but~~
406 ~~still overlap within uncertainty with~~ are largely overlapping within uncertainty with our new
407 ID-TIMS age of 2.965 ± 0.011 Ma (Fig. 7; and data in Table S7 in the supplements). The
408 apparent minor systematic offset towards slightly older ages is attributed to the lower number
409 of aliquots in the MC-ICPMS datasets combined with the heterogeneous initial Pb isotope
410 composition. ~~We speculate that the small but systematic offset between previous results and~~
411 ~~our new data may be related to natural heterogeneities that are sampled differently depending~~
412 ~~on sample size but we cannot exclude analytical differences as an additional source of bias.~~
413 ~~The origin of this bias between the two techniques should be investigated more systematically~~
414 ~~in future~~. For laser ablation U-Pb work, we recommend the use of the new ID-TIMS age
415 because of the large number of sub-samples (n=37), and the small aliquots (1-7 mg) that are
416 more representative of laser-ablation spot analysis. In addition, the use of the precisely and
417 accurately calibrated EARTHTIME tracer solutions (Condon et al., 2015) and the online mass
418 fractionation correction provided by the double Pb and double U tracer are an important
419 advantage of this method ~~compared to previous bulk analyses~~. The excellent interlaboratory

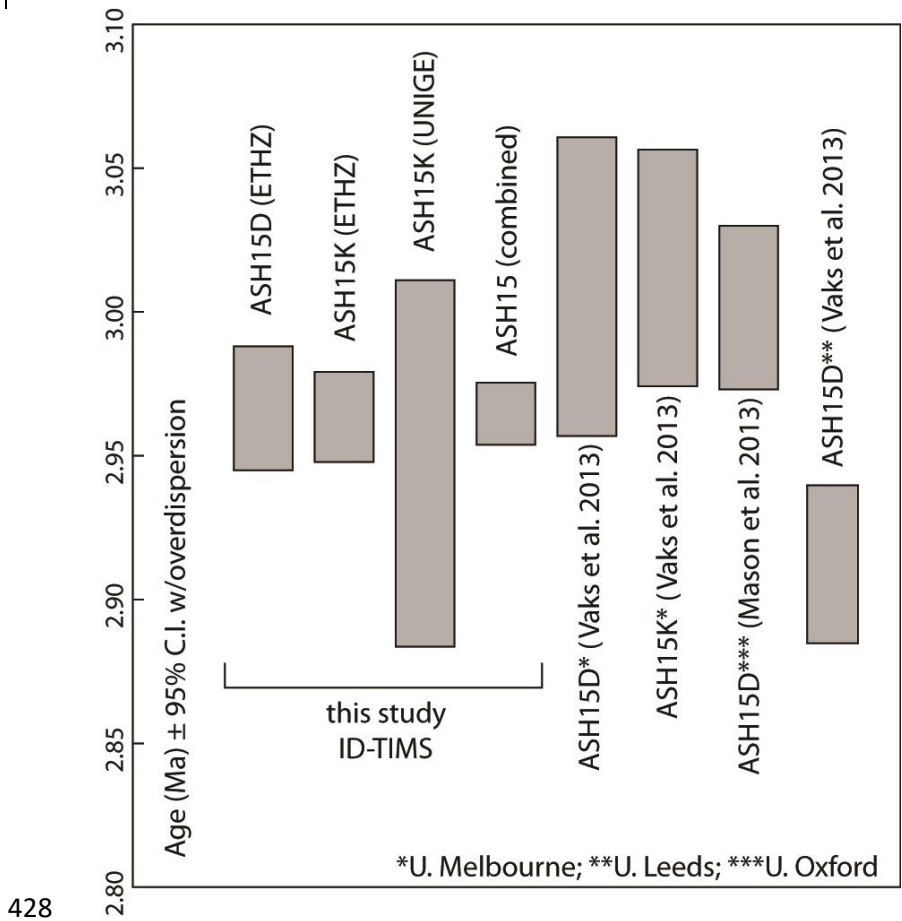

420 reproducibility gives us additional confidences that our ID-TIMS data provide the most
421 accurate characterization of the U-Pb systematics of the ASH-15 calcite for use as a primary
422 reference material.

423

424 **Figure 6.** ID-TIMS U-Pb results for ASH-15D, ASH-15K, and for both ASH-15D+K
425 displayed in Tera-Wasserburg concordia space. Uncertainties on the initial $^{207}\text{Pb}/^{206}\text{Pb}$ ratios

426 and the intercept ages are given-reported at 95% confidence as σ and as 95% confidence
427 intervals-including overdispersion (Vermeesch, 2018).

428
429 **Figure 7.** Previous (re-calculated) and new ages of ASH-15 from isotope-dilution U-Pb
430 analysis. All ages are calculated using IsoplotR (Vermeesch, 2018), and are not corrected for
431 disequilibrium and are not anchored to common-lead specific value (see data in Table S7 in
432 the supplements).

433 4.5 Calcite reference material

434 The U and Pb concentrations of carbonate materials vary greatly. Data compilation by Roberts
435 et al. (2020; this issue) combined hundreds of carbonate samples from different origin such as
436 diagenetic, biogenic, speleothem, and vein-fill. This compilation indicates several orders of
437 magnitude differences in U and Pb concentrations of the different types of carbonate and the

438 heterogeneity of spot analysis within each type or even a single sample. A modified
439 representation of their data, excluding calcite vein-fill, which vary throughout the entire
440 compositional range, is shown together with the currently available calcite reference materials
441 (Fig. 8; and full data in Table S8 in the supplement). Note that both ASH15 and JT, display
442 much larger heterogeneity when measured by LA-ICPMS (small symbols) relative to ID-TIMS
443 (large symbols). Despite the high compositional heterogeneity of each of the reference material,
444 they show minimal overlap and together they cover most of the compositional range of the
445 presented carbonate material. WC1 (Roberts et al., 2017) with relatively high U and Pb
446 concentrations can easily be measured on less-sensitive ICP-MS such as quadrupole
447 instruments, and is most appropriate to be used for dating vein-fill and diagenetic carbonates.
448 In contrast, the ASH15 flowstone, with relatively low Pb and high U concentration that are
449 better measured on more-sensitive ICP-MS (e.g. new generation of single-collector and multi-
450 collector ICP-MS), and is most appropriate for dating speleothem type carbonates. Finally the
451 JT (Guillong et al., 2020), with moderate U and Pb concentration can be used can be used for
452 most single- collector and multi-collector sector-field ICP-MS instrument as well as the newer
453 generation of quadrupole ICP-MS. Reference material with high Pb and low U or both low U
454 and Pb concentrations will further help to cover the full compositional range of carbonate
455 material but may introduce analytical challenges.

456

457

458 **Figure 8.** U and Pb concentrations of different carbonate samples and available reference
 459 materials. Large and small symbols for the reference materials indicate ID-TIMS and LA-
 460 ICPMS analyses, respectively. Note the minimal compositional overlap of the three reference
 461 materials (ASH15, WC1, and JT). Data for diagenetic, biogenic, and speleothem carbonates
 462 are from Roberts et al. (2020, this issue). Data for JT standard are from Guillong et al. (2020).

463

464 **5 Conclusions**

465 The ASH-15 speleothem calcite is characterized as a matrix matched reference material for
 466 LA-ICPMS U-Pb geochronology of calcite. ID-TIMS analyses of small 1-7 mg aliquots of two
 467 growth zones suggest sufficient homogeneity with a combined intercept age of 2.965 ± 0.011
 468 Ma and an initial $^{207}\text{Pb}/^{206}\text{Pb}$ of 0.8315 ± 0.0026 . These data are recommended as the reference
 469 values for the ASH-15 calcite reference material. The excellent agreement between the two
 470 growth zones suggest that the entire interval between the two dated layers can be used with the
 471 same reference age. Compared to other calcite reference material (e.g. WC1), ASH-15 is more

472 homogeneous but has lower radiogenic Pb content and therefore requires more sensitive
473 instruments (i.e. sector field rather than quadrupole mass spectrometers) to be used as a
474 reference material.
