17 **Abstract**

18 Latest advances in laser ablation inductively coupled plasma mass spectrometer (LA-ICPMS)  
19 allow for accurate *in-situ* U-Pb dating of carbonate material, with final age uncertainties usually  
20 >3% 2 $\sigma$ . Cross-laboratory reference materials (RMs) used for sample-bracketing are currently  
21 limited to WC1 calcite with an age of  $254.4 \pm 6.5$  (2 $\sigma$ ). The minimum uncertainty on any age  
22 determination with the LA-ICPMS method is therefore  $\geq 2.5\%$ , and validation by secondary  
23 RMs is usually performed on in-house standards. This contribution present a new reference  
24 material, ASH-15, a flowstone that is dated here by isotope dilution (ID) TIMS analysis using  
25 37 sub-samples, 1-7 mg each. Age results presented here are slightly younger compared to

26 previous ID-IRMS U-Pb dates of ASH-15, but within uncertainties and in agreement with *in-*  
27 *situ* analyses using WC1 as the primary RM. We provide new correction parameters to be used  
28 as primary or secondary standardization. The suggested  $^{238}\text{U}/^{206}\text{Pb}$  apparent age, not corrected  
29 for disequilibrium and without common-lead anchoring, is  $2.965 \pm 0.011$  Ma (uncertainties are  
30 95% confidence intervals). The new results could improve the propagated uncertainties on the  
31 final age with a minimal value of 0.4%, which is approaching the uncertainty of typical ID  
32 analysis on higher-U materials such as zircon. We show that although LA-ICPMS spot analyses  
33 of ASH-15 exhibit significant scatter in their isotopic ratios, the down-hole fractionation of  
34 ASH-15 is similar to that of other reference materials. This high-U (~1 ppm) and low Pb (<0.01  
35 ppm) calcite is most appropriate as a reference material for other speleothem-type carbonates  
36 but requires more-sensitive ICP-MS instruments such as the new generation of single-collector  
37 and multi-collector ICP-MS. Reference materials with high Pb and low U or both low U and  
38 Pb compositions are still needed to fully cover the compositional range of carbonate material  
39 but may introduce analytical challenges.

## 40 **Introduction**

41 Recent advances in laser ablation techniques applied to multi-phase carbonates allow for  
42 accurate dating of a variety of sample types, including calcite cements (Li et al., 2014; Godeau  
43 et al., 2018; Anjiang et al., 2019; Holdsworth et al., 2019), hydrothermal veins (Coogan et al.,  
44 2016; MacDonald et al., 2019; Piccione et al., 2019), fault-related veins, breccia cement, and  
45 slickenfibers (Ring and Gerdes, 2016; Roberts and Walker, 2016; Goodfellow et al., 2017;  
46 Nuriel et al., 2017; Hansman et al., 2018; Parrish et al., 2018; Nuriel et al., 2019), and  
47 speleothems (Woodhead and Petrus, 2019). With increasing attention to climatic, seismic, and  
48 environmental events in the geological record, there is a growing need for dating techniques  
49 that can be accurate and easily implemented for samples at the sub-millimeter scale. This newly

50 emerging technique has the potential to contribute to our understanding of the duration, rate,  
51 and extent of these important events in the geological record.

52 The *in-situ* approach has a great research potential for studying texturally complex samples  
53 because it can resolve problems of age mixing of different phases or averaging of continuous  
54 growth at the sub-millimeter scale, and thus increase the overall accuracy of the dated material.  
55 While the precision of traditional isotope-dilution (ID) U-Pb analyses is still favorable (<1%  
56  $2\sigma$ ) (Woodhead and Petrus, 2019), the increasing analytical development of the LA-ICPMS  
57 method indicates the potential for improving the currently reported uncertainties (usually >3%  
58  $2\sigma$ ). Finding the right matrix-matched reference material (RM) is a major hurdle for LA  
59 analyses of carbonates because of the variety of mineralogy (calcite, dolomite, and aragonite),  
60 textures, composition (e.g. high-magnesium calcite, high common-lead), and ages (e.g. low  
61 radiogenic lead in young samples). Textural differences such as microcrystalline, fine- and  
62 coarse-grained material, between the unknown and RMs can contribute to high uncertainties  
63 due to differences in ablation efficiency, down-hole fractionation, and differences in crater  
64 morphology (e.g. Guillong et al., 2020 and Elisha et al, 2020, this issue). Observed deviations  
65 are potentially up to 20% of the final intercept age depending on the degree of crater geometry  
66 mismatch and are related either to downhole fractionation and/or matrix effects (Guillong et  
67 al., 2020).

68 Currently, the most commonly used procedure for mass-bias correction in the LA method, is  
69 by standard-sample bracketing. For this, the  $^{238}\text{U}/^{206}\text{Pb}$  LA-age of the RMs is corrected to the  
70 true RM's  $^{238}\text{U}/^{206}\text{Pb}$  apparent age (not corrected for disequilibrium) as measured  
71 independently by an ID-IRMS method (ID-TIMS or ID-MC-ICPMS). The RMs are measured  
72 throughout each session along with the unknown samples, and a normalization factor is applied  
73 to correct both the RMs and the unknowns. Uncertainty propagation onto the age of the  
74 unknowns includes the uncertainties of the 'true' RM age. As a result, the accuracy of the LA

75 analyses can only be as good as the uncertainties on the age of the RMs which is by itself  
76 subjected to analytical challenges due to natural heterogeneities, impurities, and textural  
77 complexities at the sub-millimetre scale. It is therefore essential that the ‘true age’ of the  
78 reference material will reflect these complexities while maintaining minimal uncertainties.

79 Currently, several in-house standards are being used as reference materials, including Duff  
80 Brown Tank (64 Ma; Hill et al., 2016), and JT ( $13.797 \pm 0.031$  Ma; Guillong et al., 2020). The  
81 only well-characterized reference material that is distributed across laboratories is the WC1  
82 calcite with an age of  $254.4 \pm 6.5$   $2\sigma$  (2.5%) (Roberts et al., 2017). The use of WC1 alone for  
83 mass-bias correction has several disadvantages. First, it is highly recommended with all in situ  
84 U-Th-Pb geochronology to use secondary RMs to validate any correction parameters that are  
85 being used, and to appropriately propagate uncertainties. Second, the relatively high  
86 uncertainty (2.5%) on the age of WC1 sets a minimal uncertainty on any LA U-Pb age  
87 determination. Finally, the quantity of the WC1 sample that is currently available for future  
88 work is limited and is likely to not fully meet the growing demands of the LA scientific  
89 community; although we note here that there is a potential for further sample collection from  
90 the original site.

91 **1** This contribution introduces a new carbonate reference material that can be widely used  
92 for *in-situ* dating of calcite as primary or as cross-reference material with other available  
93 standards. We characterise the reference material at various resolutions using a  
94 combination of (1) laser ablation imaging (20  $\mu\text{m}$  square beam); (2) LA spot analysis,  $\sim$ 80-  
95 110  $\mu\text{m}$  in diameter, conducted on both single-collector and multi-collector (MC)  
96 inductively coupled plasma mass spectrometer (ICP-MS); and (3) ID-TIMS analyses of 37  
97 sub-samples ( $\sim$ 1-7 mg aliquots). We discuss several key issues related to the use of ASH-  
98 15 sample as a RM, including down-hole fractionation, heterogeneities, and previous bulk

99 analyses, to provide the best correction parameters and suggested protocols for users of the  
100 LA scientific community. **The ASH-15 flowstone**

101 The ASH-15 flowstone was found in Ashalim Cave, a karstic cave in the central Negev Desert  
102 (30°56'36.2" N, 34°44'22.5" E), southern Israel, which is part of the northern margin of the  
103 Saharan–Arabian desert belt. The cave entrance is located at an elevation of 414 m above sea  
104 level and 67 km SE from the Mediterranean Sea coast. The cave is a three-dimensional  
105 hypogene maze with a total length of 540 m, situated in Turonian limestone rock strata, at  
106 depths of 0-31 m below the surface. The cave is richly decorated with vadose speleothems,  
107 such as stalagmites, stalactites and flowstone, which are not active today because of the aridity  
108 of the climate in the area (Vaks et al, 2010, 2018), but periods of their deposition correspond  
109 to past episodes of wet climate in present-day desert. The thickness of the speleothems varies  
110 from several cm to a few tens of cm. The soil above the cave is silicate loess, originated mainly  
111 from aeolian dust (Crouvi et al., 2010) and the present day vegetation is composed of sparse  
112 xeric shrubs with <10% vegetation cover.

113 The vadose speleothems of Ashalim Cave are composed of low-Mg calcite, and are divided  
114 into a relatively thick Pliocene Basal layer, and thinner Pleistocene layers above it. The Basal  
115 layer varies from 5 to 25 cm in thickness and comprises c. 90% of the speleothem volume in  
116 the cave. It is composed of massive yellow calcite crystals (Fig. 1a-b), often showing  
117 continuous growth in stalagmites and flowstone, suggesting deposition from continuously  
118 dripping water. In all speleothems the Basal layer is terminated at its top by a <1 mm layer of  
119 microcrystalline calcite, evaporite minerals and reddish clays (Fig. 1a), that is interpreted as a  
120 hiatus (growth break) separating the Basal Pliocene layer and Quaternary layers above it (Vaks  
121 et al., 2013). The thickness of Pleistocene top layers varies from several mm to 17 cm, but  
122 usually does not exceed a few cm, comprising about 10% of the speleothem volume in the cave.  
123 It is composed of alternating layers of brown calcite, with the youngest top layer (where found)

124 composed of yellow calcite. Several variably colored layers <1 mm thick of microcrystalline  
125 calcite, evaporite minerals and reddish clays are found within the columnar crystalline structure,  
126 suggesting hiatuses in speleothem deposition (Vaks et al., 2013).

127 The youngest periods of speleothem deposition in several Ashalim Cave speleothems were  
128 dated by the  $^{238}\text{U}$ - $^{230}\text{Th}$  method and occurred from 221 ka to 190 ka and from 134 to 114 ka  
129 (Vaks et al, 2010). Earlier periods of deposition were dated by the U-Pb method on ASH-15  
130 flowstone at  $1.272 \pm 0.018$  Ma (ASH-15-C), and the Basal layer of ASH-15 flowstone (layers  
131 D-K) at c.  $\sim 3.1$  Ma (Fig 1a). These layers have been dated in three different labs following  
132 several protocols for ID analysis (Vaks et al., 2013; Mason et al., 2013). The U concentrations  
133 in speleothem calcite range between 1.9 and  $19.7 \mu\text{g/g}$  and the amounts of non-radiogenic Th  
134 are negligible (Vaks et al., 2010).

135  
136 **Figure 1.** Sample ASH-15 from Ashalim Cave. (a)  $\sim 5$  kg block of sample ASH-15 flowstone  
137 consisting of the massive Pliocene yellow Basal layer ( $>2$  cm calcite crystals; section D–K)  
138 and the brown Quaternary layer (top section, A–C), the thin layer between the two stratigraphic  
139 members represents a growth break (hiatus). The main U-Pb ages of Vaks et al., 2013 are  
140 indicated; (b) In-situ flowstone within Ashalim Cave from which ASH-15 was sampled,  
141 showing the large reservoir of this flowstone.

142

## 143 **2 Sample ASH-15 textural characterization**

144 The ASH-15 thin-section includes section D and E (see location in Fig.1a). Overall the thin-  
145 section examination indicates that the original texture is preserved with consistent growth  
146 direction, no observed hiatus, and no indications for dissolution and recrystallization. A spot  
147 analysis array, 85  $\mu\text{m}$  in diameter, targeted along growth zone and along growth direction is  
148 visible in Fig. 2a-c. The ASH-15 sample shows no luminescence under cathodoluminescence  
149 light (Fig. 2c), suggesting formation under oxidising conditions. The slight bright luminescence  
150 observed within grain boundaries, discontinuities, and veins (arrows in Fig. 2b-c) may suggest  
151 the presence of fluid inclusions, textural differences, or some local replacement within these  
152 areas. These areas should be avoided if possible during spot analysis. The relatively  
153 homogenous low luminescence may suggest for a single-phase continuous calcite growth,  
154 whereby precipitation occurred relatively rapid from the same fluid source (e.g. with consistent  
155  $\text{Mn}^{2+}$   $\text{Fe}^{2+}$  composition) and/or under similar precipitation redox conditions. This 15 cm thick,  
156  $\sim 3$  Ma Pliocene layer (section D-K) is essentially of the same age. For this reason, previous  
157 dating of this sample also considered a similar initial  $^{234}\text{U}/^{238}\text{U}$  activity ratio for disequilibrium  
158 correction (Mason et al., 2013; Vaks et al., 2013). The ASH-15 reference material consists of  
159 the whole Pliocene section that terminates with a sharp transition to the darker Pleistocene  
160 layers above it (section A-C; see Fig. 1b). About 3 kg of ASH-15 sample are excavated from  
161 the Ashalim Cave (Fig. 1a), and potentially much more can be sampled in the future (we  
162 estimate more than 10 kg of sample; Fig. 1b). The ASH-15 flowstone is therefore a good  
163 candidate for a reference material because of its large volume, high U concentrations, and  
164 potentially homogenous age which will be examine next.

165

166 **Figure 2.** ASH-15D-E thin-section. (a) cross-polarized (XPL) scan , 36 mm long, showing  
 167 continuous growth (no hiatus), and consistent growth direction (indicated with yellow arrow).  
 168 Spot analyses are targeted either sub-parallel to growth zone or sub-parallel to growth direction;  
 169 (b) close-up on spot array analyses (location is shown in a) with 85 μm diameter; (c) CL image  
 170 showing no luminescence except for some bright luminescence within grains boundaries and  
 171 veins (arrows).

### 172 3 Methods

#### 173 3.1 Elemental mapping

174 The sample ASH-15 was cut perpendicular to the growth zone of section D and E (see Fig.1b)  
 175 in order to examine heterogeneities across growth zone and within. Thin-sections were then  
 176 examined under plane- and cross-polarized light (XPL/PPL), and cathodoluminescence (CL)  
 177 microscopy (Fig. 2). The central part of the thin-section was also analyzed for elemental  
 178 distribution of selected elements. The elemental maps were measured via LA-ICPMS, carried  
 179 out on a 193 nm ArF excimer laser ablation system (Analyte G2 Teledyne Photon Machines  
 180 Inc., Bozeman MT) coupled to an ICP-QMS (Agilent 7900, Agilent Technologies, Santa Clara  
 181 CA). The laser was equipped with a Photon Machines HelEx II ablation chamber and an  
 182 Aerosol Rapid Introduction System (ARIS). The experiments were carried out using  
 183 acquisition parameters (both on the ICP and on the laser) modelled using the approach of van

184 Elteren et al (2019; 2018) to avoid artefacts (e.g., aliasing, smear, blur). All images (500x500  
185 pixels) were acquired using a 20  $\mu\text{m}$  square beam, fluence of  $3.5 \text{ Jcm}^{-2}$ , 294 Hz repetition rate  
186 and dosage of 10 (10 overlapping pulses per spot size which amount to a scanning speed of  
187  $588 \mu\text{ms}^{-1}$ ). The masses monitored were  $^{88}\text{Sr}$ ,  $^{137}\text{Ba}$ ,  $^{206}\text{Pb}$ ,  $^{208}\text{Pb}$ ,  $^{232}\text{Th}$ , and  $^{238}\text{U}$  and the  
188 images were constructed using Photon Machines' HDIP data reduction software (van Malderen,  
189 2017).

### 190 3.2 LA-MC-ICPMS spot analyses

191 A thin section of ASH-15 was dated by U-Pb laser ablation multi-collector inductively coupled  
192 plasma mass spectrometry (LA-MC-ICPMS) following the method described in Nuriel et al.  
193 (2017). A Nu Plasma 3D was employed in conjunction with a Photon Machines Excite 193nm  
194 Excimer laser equipped with a HelEx two volume cell. The laser was fired for 15 s during  
195 analysis, using a repetition rate of 10 Hz, a spot size of  $85 \mu\text{m}$ , and a fluence of approx.  $1 \text{ J/cm}^2$ .  
196 The Nu Plasma 3D allows for the simultaneous acquisition of  $^{238}\text{U}$ ,  $^{235}\text{U}$ ,  $^{232}\text{Th}$ ,  $^{208}\text{Pb}$ ,  $^{207}\text{Pb}$ ,  
197  $^{206}\text{Pb}$ ,  $^{204}\text{Pb}(\text{+Hg})$ , and  $^{202}\text{Hg}$ , where  $^{238}\text{U}$ - $^{232}\text{Th}$  are measured on Faraday detectors and the low-  
198 side masses are measured on Daly detectors. Instrumental mass-bias was corrected using a  
199 two-step approach: both the  $^{207}\text{Pb}/^{206}\text{Pb}$  and  $^{206}\text{Pb}/^{238}\text{U}$  ratios were first corrected to NIST-614  
200 glass reference material in *Iolite 3* using the geochronology reduction scheme (Paton et al.,  
201 2010) to account for both mass-bias ( $^{207}\text{Pb}/^{206}\text{Pb}$ ) and instrumental drift ( $^{207}\text{Pb}/^{206}\text{Pb}$  and  
202  $^{206}\text{Pb}/^{238}\text{U}$ ). The Tera-Wasserburg data, output from *Iolite*, was then plotted and  $^{206}\text{Pb}/^{238}\text{U}$   
203 ratios of all RMs and unknowns were adjusted such that the primary calcite reference  
204 material—WC-1—yielded an age of 254 Ma (Roberts et al., 2017). This resulted in accurate  
205 dates for both our secondary calcite RM: Duff Brown Tank at  $66.8 \pm 3.4 \text{ Ma}$  (previously  
206 reported 64 Ma; Hill et al., 2016) and a  $^{207}\text{Pb}/^{206}\text{Pb}$  date of zircon RM at  $566.0 \pm 2.8 \text{ Ma}$   
207 (previously reported 564 Ma; Gehrels et al., 2008). Uncertainty propagation of individual ratios  
208 was assessed by reproducibility of the NIST614 and SL RMs (n=44 in both cases) and added

209 in quadrature such that the MSWD of each weighted average is  $\leq 1$  and that the uncertainty is  
210 no better than 2% (long-term reproducibility); this resulted in propagated uncertainties of 2.5%  
211 and 2% for the  $^{206}\text{Pb}/^{238}\text{U}$  and  $^{207}\text{Pb}/^{206}\text{Pb}$  ratios, respectively. Given that the typical  
212 uncertainties of the  $^{206}\text{Pb}/^{238}\text{U}$  and  $^{207}\text{Pb}/^{206}\text{Pb}$  ratios of the unknowns was  $>10\%$  and  $>3\%$ ,  
213 respectively, the uncertainty propagation on individual ratios had little effect on the calculation  
214 of the final date of ASH-15. The thin section of ASH-15 was measured both parallel to the  
215 length of section (303 spots, and perpendicular to it (101 spots). Data are plotted using Isoplot  
216 (Ludwig, 1998).

217

### 218 **3.3 LA-ICPMS spot analyses**

219 Analyses were conducted at the Geochronology and Tracers Facility, British Geological  
220 Survey (Nottingham, UK). The instrumentation comprised a New Wave Research 193UC  
221 excimer laser ablation system fitted with a TV2 cell, coupled to a Nu Instruments Attom single  
222 collector ICP-MS. The method follows the protocols described in Roberts and Walker (2016)  
223 and Roberts et al. (2017). Laser parameters varied slightly per session, but typically involve a  
224 pre-ablation cleaning spot of 150  $\mu\text{m}$ , fired at 10 Hz with a fluence of  $\sim 6 \text{ J/cm}^2$  for 2 seconds,  
225 and ablation conditions of 80-100  $\mu\text{m}$  spots, fired at 10 Hz with a fluence of  $\sim 6-8 \text{ J/cm}^2$  for 25-  
226 30 seconds. A 60 second background is taken before every set of standard-bracketed analyses,  
227 and a 5 second washout is left between each ablation. Normalization of Pb-Pb ratios is achieved  
228 using NIST614 glass (values of Woodhead and Hergt, 2001), and WC-1 carbonate for Pb-U  
229 ratios (Roberts et al., 2017). Data reduction uses the Time Resolved Analysis function of the  
230 Nu Instruments Attolab software, and an excel spreadsheet, with uncertainty propagation  
231 following the recommendations of Horstwood et al. (2016).

232

### 233 3.4 ID-TIMS U-Pb geochronology

234 Isotope dilution thermal ionization mass spectrometry (ID-TIMS) U-Pb geochronology was  
235 performed at the Institute of Geochemistry and Petrology of ETH Zurich (ETHZ) and at the  
236 Department of Earth Sciences of the University of Geneva (UNIGE). Millimetre-sized chips  
237 of the ASH-15-D and ASH-15-K calcite were extracted using stainless steel tools. Larger chips  
238 were further sub-divided resulting in ~1-7 mg aliquots. Individual chips were transferred into  
239 3 ml Savillex beakers and repeatedly ultrasonically cleaned in ultrapure acetone and water.  
240 Cleaned samples were transferred into pre-cleaned 3 ml Savillex beakers, spiked with ~5-10  
241 mg EARTHTIME ( $^{202}\text{Pb}$ - $^{205}\text{Pb}$ - $^{233}\text{U}$ - $^{235}\text{U}$  tracer solution (Condon et al., 2015) and dissolved  
242 in 6N HCl at 120°C on a hotplate for ~30 minutes to assure complete dissolution and sample-  
243 spike equilibration. Dissolved samples were dried down and redissolved in 1N HBr. Uranium  
244 and Pb were separated using a single-column (50  $\mu\text{l}$ , AG1-X8 resin) HBr-HCl anion exchange  
245 chemistry. The Pb fraction was dried down with a drop of  $\text{H}_3\text{PO}_4$  after a single column pass.  
246 Uranium was dried down, redissolved in 3N HCl and further purified with a HCl-based second  
247 column pass before drying it down with a drop of  $\text{H}_3\text{PO}_4$ . Uranium and Pb were loaded on  
248 outgassed single Re filaments with ~1  $\mu\text{l}$  of Si-gel emitter for thermal ionization mass  
249 spectrometry. Uranium and Pb isotope ratios were measured on a Thermo TRITON Plus at  
250 ETHZ and a Thermo TRITON at UNIGE. Lead isotopes were measured on the axial secondary  
251 electron multiplier employing dynamic peak-hopping routine collecting masses (202), 204, 205,  
252 206, 207 and 208. Measured Pb isotope ratios were corrected for mass fractionation either using  
253 the double spike (ETHZ) or using a mass fractionation factor of  $0.15 \pm 0.03 \text{ ‰/amu}$  for single  
254 Pb spiked samples (UNIGE). Uranium isotope ratios were measured as uranium-oxide ( $\text{UO}_2$ )  
255 employing a static measurement routine with Faraday cups connected to amplifiers with  $10^{13}$   
256 ohm feedback resistors (von Quadt et al., 2016; Wotzlaw et al., 2017). Isotope ratios were  
257 corrected for isobaric interferences from minor  $\text{UO}_2$  isotopologues (Wotzlaw et al., 2017) and

258 for mass fractionation using the double spike assuming a  $^{238}\text{U}/^{235}\text{U}$  ratio of  $137.818 \pm 0.045$   
259 (Hiess et al., 2012) for sample and blank. Total procedural Pb blanks for the HBr-based  
260 chemistry at ETHZ are consistently between 0.2 and 0.4 pg. We therefore attribute up to 0.4  
261 pg to laboratory blank with the remaining common Pb being attributed to initial common Pb.  
262 Total procedural blanks measured at UNIGE yielded an average of 1.15 pg that was taken as  
263 the laboratory blank contribution. Data reduction and uncertainty propagation was performed  
264 using Tripoli and an Microsoft Excel-based spreadsheet that uses the algorithms of Schmitz  
265 and Schoene (2007). Isochron calculations were performed using IsoplotR (Vermeesch, 2018).  
266 All uncertainties are reported at 95% confidence ignoring systematic uncertainties associated  
267 with the tracer calibration and decay constants unless otherwise stated.

## 268 **4 Results**

269 All analyses were performed on ASH-15-D-K yellow Pliocene layer, abbreviated here as  
270 “ASH-15” unless specification of ASH-15-D, E etc. is indicated. The ASH-15-A-C brown  
271 Pleistocene layer is not part of the ASH-15 suggested reference material.

### 272 **4.1 LA elemental mapping**

273 Elemental mapping for  $^{88}\text{Sr}$ ,  $^{137}\text{Ba}$ ,  $^{206}\text{Pb}$ ,  $^{208}\text{Pb}$ ,  $^{238}\text{U}$  and  $^{238}\text{U}/^{206}\text{Pb}$  ratio shows that the  
274 distribution of most elements is relatively homogeneous (Fig.3), and in good accordance with  
275 the luminescence data. Higher intensities for  $^{238}\text{U}$  and  $^{88}\text{Sr}$  were observed along grain  
276 boundaries and discontinuities, whereas Pb and the rest of the trace elements are more  
277 homogeneously distributed, arguing for steady environmental conditions during the deposition.  
278 Ten random regions of interest (ROI) were selected throughout the sample to mimic 10 spot  
279 analysis carried out at 85-90 microns spot size – just like one would do for U-Pb geochronology.  
280 These ROIs were generated by drawing on the map circular regions with the radius of 85 or 90  
281 microns in diameter. The pixels comprising each ROI were pooled together as representing the

282 equivalent of a single spot analysis. The statistical data for each cluster (data are given in  
 283 supplementary file) were compared. The average values for all pixel data are within 2 standard  
 284 errors and in good agreement, indicating that, at least based on the elemental distribution we  
 285 measured, the sample is relatively homogeneous for a natural sample. To further investigate  
 286 the chemical homogeneity of the sample, a random transect through one of the growth zones  
 287 was drawn and the signal intensities for  $^{238}\text{U}$  were extracted. The transect data also indicate  
 288 that  $^{238}\text{U}$  variations are within 2 standard errors of the average value (full data is available in  
 289 Table S1 in the supplement).

290

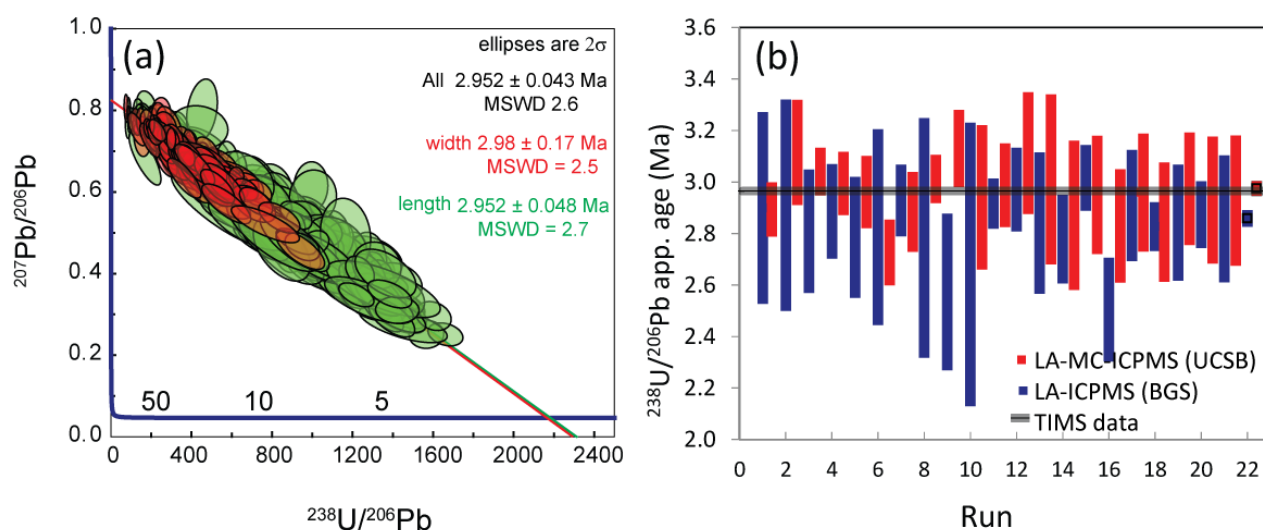

291 **Figure 3.** Signal intensity maps of ASH-15. For  $^{238}\text{U}/^{206}\text{Pb}$ ,  $^{88}\text{Sr}$ ,  $^{137}\text{Ba}$ ,  $^{206}\text{Pb}$ ,  $^{208}\text{Pb}$ , and  $^{238}\text{U}$   
 292 (a-d). The plotted signal was corrected for blank and analytical drift of the instrumentation.  
 293 Note that each distribution map has its own signal intensity scale. The position of the regions  
 294 of interest and transect is shown in (a). The circles designating the location of the regions of  
 295 interest are not at scale (data is available in Table S1 in the supplement).

296 **4.2 LA-MC-ICPMS spot analyses**

297 Data and calculated ages for the LA-MC-ICPMS transects are shown in Tera-Wasserburg  
298 space in Fig. 4 (n = 379 of 412 total spots). Analyses rejected from the age calculation include  
299 those with  $^{207}\text{Pb}/^{206}\text{Pb}$  uncertainties larger than 0.1% (n = 2) and those with high common-Pb  
300 contents ( $^{208}\text{Pb}$  cps >5000; n = 17). A further 14 spots plotted below the array; these data  
301 represent the first 1–2 mm of spots of the lengthwise transect (lower right in Fig. 2a), and  
302 suggest that a small percent of ASH-15 may behave differently during ablation and/or may  
303 have been subsequently modified after crystallization; upon inspection, this portion of the  
304 section contains more pore space and impurities than the majority of the section. The remaining  
305 379 define a normally distributed array with a lower intercept age of  $2.952 \pm 0.043$  Ma (MSWD  
306 = 2.5), which is well within uncertainty of the new ID-TIMS data presented (full data is  
307 available in Table S2 in the supplement). The calculated upper intercept of each transect is  
308 equivalent and within 1% of the common Pb composition calculated from the ID-TIMS data.  
309 Not surprisingly, the lengthwise transect reveals a larger spread in common/radiogenic Pb  
310 ratios; this transect crosses more growth zones and has a higher probability of sampling a  
311 variety of concentrations of both Pb and U. Conversely, the more limited spread in  
312 common/radiogenic Pb ratios appears to reflect the limited sampling of growth zones, and  
313 would suggest that individual growth zones contain a relatively limited range of concentrations  
314 in U and Pb. The slightly higher MSWD for the lengthwise transect (2.7) relative to the growth  
315 zone transect (2.5) could also reflect these inherited compositional differences during growth  
316 history, and a resulted “mixing” or “averaging” of different growth phase along calcite  
317 continuous growth.

318 Variations of ASH-15 ages during 20 different runs (with 5-30 spot analysis in each) using  
319 both single-collector and multi-collector ICP-MS are shown in Fig. 4b (full data is available in  
320 Tables S3-S5 in the supplement). The ages are calculated using IsoplotR, not anchored to  
321 specific common-lead, and are not corrected for disequilibrium. Although there is a large

322 scatter in the ages of the different runs the average ages (marked with black box) plot close to  
 323 the new ID-TIMS ages, or are slightly younger in age.

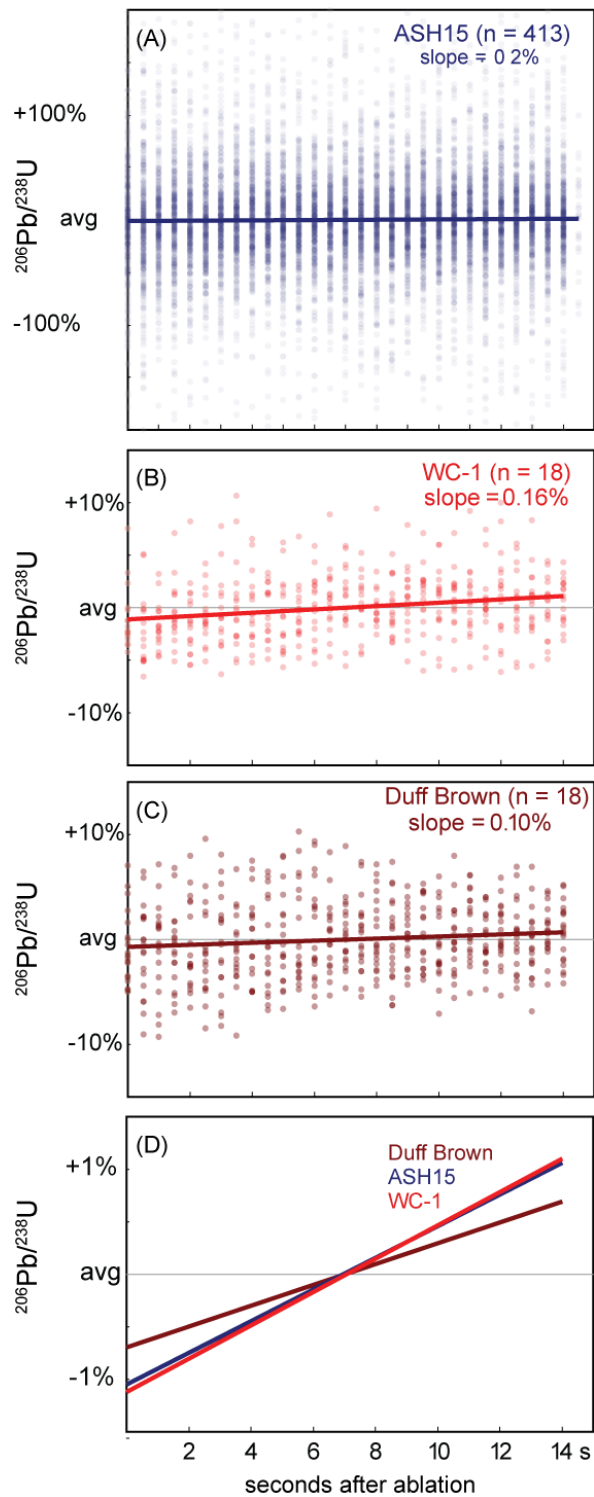

324  
 325 **Figure 4.** LA-MC-ICPMS analyses of calcite ASH-15. (a) Tera-Wasserburg concordia space  
 326 plot (n=385) for spots analysis within lengthwise transect (green) and along growth zone  
 327 transect (red). Calculated age, 2 $\sigma$  error and MSWD are given for both and for all spots together;  
 328 (full data is available in Table S2 in the supplement); (b) Variations of ASH-15 ages during  
 329 different runs using both single-collector (at the British Geological Survey) and multi-collector  
 330 (at University of California Santa Barbara) ICP-MS. Ages are calculated using WC1 as primary  
 331 RM; the new ID-TIMS age is indicated with a grey line; (full data is available in Table S3-S5  
 332 in the supplement).

### 333 4.3 Down-hole fractionation

334 Reference material is important for correction of both laser-induced elemental fractionation  
 335 (LIEF) and plasma-related ionization efficiency. Ideally, the reference material should  
 336 resemble the unknown samples as much as possible in terms of its chemistry (e.g. Mg and Fe  
 337 content), texture (i.e. micritic, crystalline), and age. The WC1 and ASH15 are both low-Mg  
 338 calcite but they are very different in textures and age. The ASH15 is a ~3 Ma, well-crystallized  
 339 elongated calcite (up to 1 cm) and WC1 is a 254 Ma recrystallized botryoidal calcite, formed

340 after aragonite. Despite these differences, both WC1 and ASH15 display a very similar down-  
341 hole fractionation pattern (Fig. 5d). Fig. 5 shows stacked integration plots of the down-hole  
342 raw  $^{206}\text{Pb}/^{238}\text{U}$  ratio of different RMs including, the ASH15, WC-1, and Duff Brown Tank  
343 (Black and Gulson, 1978). The ASH15 displays much larger scatter in the raw data (Fig. 5a) in  
344 comparison to both WC1 and Duff Brown Tank (Fig. 5b-c), however, the average value yielded  
345 identical down-hole fractionation to that of WC-1 (Fig. 5d). Duff Brown Tank is also consistent  
346 with the down-hole patterns but less steep in comparison to WC1 and ASH15 (Fig. 5d). This  
347 comparison suggests that down-hole fractionation and laser-induced elemental fractionation  
348 (LIEF) are similar among the different RMs. It is thus suggested that differences in measured  
349 and expected  $^{206}\text{Pb}/^{238}\text{U}$  ratios in calcite material are likely to be caused mostly by plasma-  
350 ionization differences between unknown samples and RMs.

351

352 **Figure 5.** Stacked integration plots of raw  $^{207}\text{Pb}$ -corrected  $^{206}\text{Pb}/^{238}\text{U}$  ratios for calcite reference  
 353 materials ASH-15, WC-1, and Duff Brown Tank. The low Pb concentration in ASH-15 yields  
 354 more scatter, but average slopes of all RMs are similar, with 1-2% change in age over 10  
 355 seconds (100 pulses) of ablation. The results suggest minimal differences in down-hole  
 356 fractionation of the different RMs.

#### 357 4.4 ID-TIMS results

358 Twelve aliquots of ASH-15D analyzed at ETHZ yielded  $^{238}\text{U}/^{206}\text{Pb}$  ratios between 1096 and  
359 2084 and  $^{207}\text{Pb}/^{206}\text{Pb}$  ratios between 0.0825 and 0.4403 (full data is available in Table S6 in the  
360 supplement). Plotted in Tera-Wasserburg space, these data yield a single isochron with an  
361 initial  $^{207}\text{Pb}/^{206}\text{Pb}$  of  $0.832 \pm 0.015$  (uncertainties are 95% confidence intervals) and a concordia  
362 intercept age of  $2.967 \pm 0.022$  Ma (Fig. 6a). The elevated mean square weighted deviation  
363 (MSWD) of 12 is attributed to minor heterogeneities, most likely in the initial  $^{207}\text{Pb}/^{206}\text{Pb}$  ratio  
364 of the speleothem calcite. Twelve aliquots of ASH-15K analyzed at ETHZ returned  $^{238}\text{U}/^{206}\text{Pb}$   
365 ratios between 723 and 2094 and  $^{207}\text{Pb}/^{206}\text{Pb}$  ratios between 0.0720 and 0.5677. In Tera-  
366 Wasserburg space, eleven out of twelve aliquots define a isochron with an initial  $^{207}\text{Pb}/^{206}\text{Pb}$  of  
367  $0.8314 \pm 0.0040$  and a concordia intercept age of  $2.964 \pm 0.016$  Ma (Fig. 6b). A single aliquot  
368 (#5.4) plots significantly below the isochron defined by the other aliquots. The elevated MSWD  
369 of 34 together with the single outlier suggest some heterogeneities in the initial  $^{207}\text{Pb}/^{206}\text{Pb}$  of  
370 the ASH-15K calcite. Thirteen aliquots of ASH-15K analyzed at UNIGE (pink color, Fig. 6b)  
371 yielded  $^{238}\text{U}/^{206}\text{Pb}$  ratios between 433 and 1853 and  $^{207}\text{Pb}/^{206}\text{Pb}$  ratios ranging from 0.1856  
372 to 0.6660. Twelve of the thirteen analyses yield best-fit line with an initial  $^{207}\text{Pb}/^{206}\text{Pb}$  of  $0.814$   
373  $\pm 0.019$  and a Concordia intercept age of  $2.947 \pm 0.065$  Ma. The elevated MSWD of 36  
374 confirms the minor heterogeneity of the initial  $^{207}\text{Pb}/^{206}\text{Pb}$ .

375 The excellent agreement between the ASH-15D and ASH-15K datasets indicates that the entire  
376 speleothem growth layer between these two growth zones is of equivalent age with minor  
377 heterogeneities in the initial  $^{207}\text{Pb}/^{206}\text{Pb}$  ratio and justifies combining the data into a single  
378 isochron regression. The combined isochron, using 35 of 37 analyzed aliquots, yields an initial  
379  $^{207}\text{Pb}/^{206}\text{Pb}$  of  $0.8306 \pm 0.0033$  and a concordia intercept age of  $2.965 \pm 0.011$  Ma with a  
380 MSWD of 35 (Fig. 6c). We consider the results of the combined regression as the best reference  
381 value for using ASH-15 as a primary reference material.

382 The new TIMS data provide the most extended bulk investigation of the ASH-15 sample, with  
383 a total of 37 sub-samples that are separated from bottom (K, n=25) to top (D, n=12). The high  
384 MSWD of 35 is suggested to reflect true heterogeneities of the dated material, possibly related  
385 to impurities that are concentrated within grain boundaries (as suggested by CL and elemental  
386 mapping). We re-calculated previously determined isochron ages of Vaks et al. (2013) and  
387 Mason et al. (2013; Fig. 7). We obtained concordia intercept ages of  $3.0088 \pm 0.053$  Ma for  
388 ASH-15-D (MSWD=11; n=5) and  $3.0153 \pm 0.042$  Ma for ASH-15-K (MSWD=14; n=5) of  
389 Vaks et al. (2013) and  $3.0015 \pm 0.029$  for ASH-15-D (MSWD=2; n=5) of Mason et al. (2013).  
390 These ages are largely overlapping within uncertainty with our new ID-TIMS age of  $2.965 \pm$   
391  $0.011$  Ma (Fig. 7; and data in Table S7 in the supplements). The apparent minor systematic  
392 offset towards slightly older ages is attributed to the lower number of aliquots in the MC-  
393 ICPMS datasets combined with the heterogeneous initial Pb isotope composition. For laser  
394 ablation U-Pb work, we recommend the use of the new ID-TIMS age because of the large  
395 number of sub-samples (n=37), and the small aliquots (1-7 mg) that are more representative of  
396 laser-ablation spot analysis. In addition, the use of the precisely and accurately calibrated  
397 EARTHTIME tracer solutions (Condon et al., 2015) and the online mass fractionation  
398 correction provided by the double Pb and double U tracer are an important advantage of this  
399 method. The excellent interlaboratory reproducibility gives us additional confidences that our  
400 ID-TIMS data provide the most accurate characterization of the U-Pb systematics of the ASH-  
401 15 calcite for use as a primary reference material.

402

403 **Figure 6.** ID-TIMS U-Pb results for ASH-15D, ASH-15K, and for both ASH-15D+K  
 404 displayed in Tera-Wasserburg concordia space. Uncertainties on the initial  $^{207}\text{Pb}/^{206}\text{Pb}$  ratios  
 405 and the intercept ages are reported at 95% confidence including overdispersion (Vermeesch,  
 406 2018).

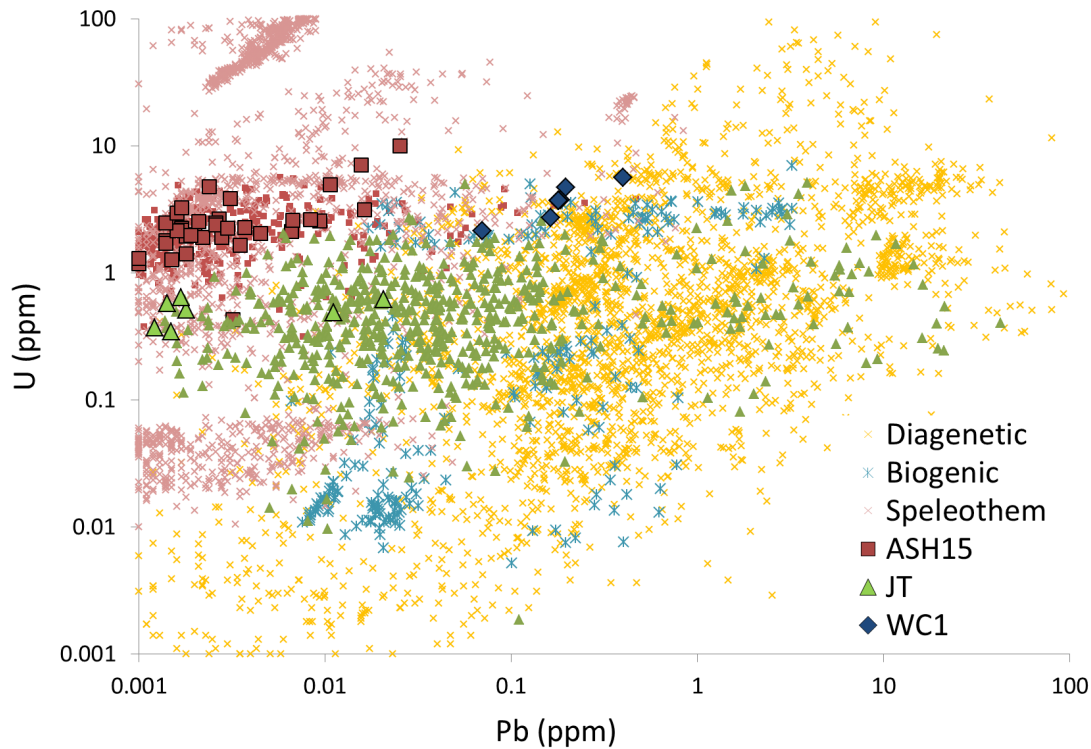

407  
 408 **Figure 7.** Previous (re-calculated) and new ages of ASH-15 from isotope-dilution U-Pb  
 409 analysis. All ages are calculated using IsoplotR (Vermeesch, 2018), are not corrected for  
 410 disequilibrium and are not anchored to common-lead specific value (see data in Table S7 in  
 411 the supplements).

412 **4.5 Calcite reference material**

413 The U and Pb concentrations of carbonate materials vary greatly. Data compilation by Roberts  
 414 et al. (2020; this issue) combined hundreds of carbonate samples from different origin such as  
 415 diagenetic, biogenic, speleothem, and vein-fill. This compilation indicates several orders of  
 416 magnitude differences in U and Pb concentrations of the different types of carbonate and the  
 417 heterogeneity of spot analysis within each type or even a single sample. A modified  
 418 representation of their data, excluding calcite vein-fill, which vary throughout the entire

419 compositional range, is shown together with the currently available calcite reference materials  
420 (Fig. 8; and full data in Table S8 in the supplement). Note that both ASH15 and JT, display  
421 much larger heterogeneity when measured by LA-ICPMS (small symbols) relative to ID-TIMS  
422 (large symbols). Despite the high compositional heterogeneity of each of the reference material,  
423 they show minimal overlap and together they cover most of the compositional range of the  
424 presented carbonate material. WC1 (Roberts et al., 2017) with relatively high U and Pb  
425 concentrations can easily be measured on less-sensitive ICP-MS such as quadrupole  
426 instruments, and is most appropriate to be used for dating vein-fill and diagenetic carbonates.  
427 In contrast, the ASH15 flowstone, with relatively low Pb and high U concentration that are  
428 better measured on more-sensitive ICP-MS (e.g. new generation of single-collector and multi-  
429 collector ICP-MS), and is most appropriate for dating speleothem type carbonates. Finally the  
430 JT (Guillong et al., 2020), with moderate U and Pb concentration can be used can be used for  
431 most single- collector and multi-collector sector-field ICP-MS instrument as well as the newer  
432 generation of quadrupole ICP-MS. Reference material with high Pb and low U or both low U  
433 and Pb concentrations will further help to cover the full compositional range of carbonate  
434 material but may introduce analytical challenges.

435

436

437 **Figure 8.** U and Pb concentrations of different carbonate samples and available reference  
 438 materials. Large and small symbols for the reference materials indicate ID-TIMS and LA-  
 439 ICPMS analyses, respectively. Note the minimal compositional overlap of the three reference  
 440 materials (ASH15, WC1, and JT). Data for diagenetic, biogenic, and speleothem carbonates  
 441 are from Roberts et al. (2020, this issue). Data for JT standard are from Guillong et al. (2020).

442

## 443 5 Conclusions

444 The ASH-15 speleothem calcite is characterized as a matrix matched reference material for  
 445 LA-ICPMS U-Pb geochronology of calcite. ID-TIMS analyses of small 1-7 mg aliquots of two  
 446 growth zones suggest sufficient homogeneity with a combined intercept age of  $2.965 \pm 0.011$   
 447 Ma and an initial  $^{207}\text{Pb}/^{206}\text{Pb}$  of  $0.8315 \pm 0.0026$ . These data are recommended as the reference  
 448 values for the ASH-15 calcite reference material. The excellent agreement between the two  
 449 growth zones suggest that the entire interval between the two dated layers can be used with the  
 450 same reference age. Compared to other calcite reference material (e.g. WC1), ASH-15 is more

451 homogeneous but has lower radiogenic Pb content and therefore requires more sensitive  
452 instruments (i.e. sector field rather than quadrupole mass spectrometers) to be used as a  
453 reference material.
