11

12 **Abstract**

13 Analysis of cosmogenic nuclides produced in surface rocks and sediments is a valuable tool for  
14 assessing rates of processes and the timing of events that shaped the Earth surface. The various nuclides  
15 that are used have specific advantages and limitations that depend on the time-range over which they are  
16 useful, the type of material they are produced in, and not least the feasibility of the analytical effort.  
17 Anticipating novel applications in Earth surface sciences, we develop in-situ produced terrestrial  
18 cosmogenic krypton ( $Kr_{it}$ ) as a new tool; the motivation being the availability of six stable and one  
19 radioactive isotope ( $^{81}Kr$ , half-life 229 kyr) and of an extremely weathering-resistant target mineral  
20 (zircon). We provide proof of principle that terrestrial  $Kr_{it}$  can be quantified and used to unravel Earth  
21 surface processes.

22

23 **1 Introduction**

24 Cosmogenic nuclides have become an important tool to address questions in Earth surface sciences and  
25 paleoclimatology (Dunai, 2010; Gosse and Phillips, 2001; Balco, 2020). These nuclides are produced by  
26 particles of the cosmic ray cascade in the atmosphere and in minerals (i.e., in situ) at or close to the  
27 Earth's surface (Dunai, 2010; Gosse and Phillips, 2001). Each of the currently applied in-situ produced  
28 cosmogenic nuclides, i.e.,  $^3He$ ,  $^{10}Be$ ,  $^{14}C$ ,  $^{21}Ne$ ,  $^{26}Al$ ,  $^{36}Cl$ , and  $^{53}Mn$ , has specific benefits and limitations  
29 that are rooted in its half-life, or stability in the case of  $^3He$  and  $^{21}Ne$ , the availability of suitable target  
30 minerals and our ability to measure the exceedingly low amounts produced (typically between 1-100  
31 atoms per gram per year at sea level (Dunai, 2010)). In space, production rates are at least three orders of  
32 magnitude higher than on Earth at ground-level. Hence, many in-situ produced nuclides were initially  
33 developed in studies of extra-terrestrial material (e.g., meteorites, lunar rocks) some thirty years before  
34 they began to be used to transform quantitative Earth surface sciences. Cosmogenic krypton,  $^{78,80-86}Kr$   
35 (Marti et al., 1966; Gilabert et al., 2002; Marti, 1967) has not made this transition yet, despite having the  
36 potential. Krypton is the only noble gas that has stable ( $^{78,80,82-84,86}Kr$ ) and short-lived radioactive

37 isotopes ( $^{81,85}\text{Kr}$ ) that are produced by cosmic rays (Gilbert et al., 2002; Marti et al., 1966). With a half-  
38 live ( $T_{1/2}$ ) of  $229 \pm 11$  kyr (Baglin, 2008),  $^{81}\text{Kr}$  is particularly attractive for geomorphological  
39 applications, however, only the cosmogenic  $^{81}\text{Kr}$  produced in the atmosphere has been used in Earth  
40 sciences to date, as a dating tool for old ice and groundwater (Buizert et al., 2014; Sturchio et al., 2004).

41

#### 42 **1.1 In situ produced *extra-terrestrial* krypton**

43 In situ produced extra-terrestrial krypton,  $\text{Kr}_{\text{iet}}$ , in meteorites has been measured for over fifty years  
44 (Marti et al., 1966; Marti, 1967). For instance, the Kr-Kr dating method of meteorites (Marti, 1967) is  
45 routinely applied (e.g., Strashnov and Gilmour, 2013; Leya et al., 2015). All stable and moderately long-  
46 lived Krypton isotopes (including  $^{85}\text{Kr}$ ,  $T_{1/2} = 10.7$  yr, (Lerner, 1963)) are produced via spallation  
47 reactions (Gilbert et al., 2002) that are responsible for cosmogenic production. The main target  
48 elements for spallogenic Kr-production are Rb, Sr, Y, Zr and Nb (Gilbert et al., 2002; Marti et al.,  
49 1966; Leya et al., 2015), which have isotopes similar in mass (slightly higher masses) to Kr-isotopes.  
50 The minimum energies for neutrons producing Kr-isotopes by spallation from Zr are 50 - 100 MeV  
51 (higher end of range for isotope masses  $< 83$  (Gilbert et al., 2002)).

52

#### 53 **1.2 In situ produced terrestrial krypton**

54 In meteorites, Rb, Sr, Y, Zr and Nb are trace constituents at the ppm level (Mason et al., 1976; Leya et  
55 al., 2004). A key conceptual step in utilizing in situ produced terrestrial krypton,  $\text{Kr}_{\text{it}}$ , is the realization  
56 that, due to the geochemical differentiation of the Earth, the target elements for cosmogenic Kr form  
57 discrete minerals, or are enriched in other minerals. For example: Rb is enriched in biotite; Sr forms  
58 strontianite ( $\text{SrCO}_3$ ), strontian calcite (up to several % Sr) or coelestine ( $\text{SrSO}_4$ ); Y forms xenotime  
59 ( $\text{YPO}_4$ ); Zr zircon ( $\text{ZrSiO}_4$ ) and baddeleyite ( $\text{ZrO}_2$ ); and Nb is present in columbite ( $(\text{Fe}, \text{Mn}, \text{Mg})\text{Nb}_2\text{O}_6$ ).  
60 Enrichments in these minerals over the concentrations in meteorites may be in the order of  $10^3 - 10^4$ ,  
61 similar in magnitude to the cosmic ray flux differences between space and on Earth (Dunai, 2010), but  
62 in a reversed sense. The lower cosmic ray flux on Earth is thus fully compensated by the higher target-  
63 element concentrations and so determination of  $\text{Kr}_{\text{it}}$  in these minerals should be as easily attainable as  
64  $\text{Kr}_{\text{iet}}$  is in meteorites.

65

66 Given the list of potential minerals, it appears that only zircon is near-ubiquitous on the Earth's surface,  
67 albeit as accessory mineral. Therefore, in the following we focus on zirconium as the target element and  
68 zircon as the target mineral. Considerations for other target elements/minerals are conceptually similar.

69

##### 70 **1.2.1 Spallation**

71 As a first approximation of terrestrial production of krypton by spallation of zirconium due to neutrons  
72 we use thick target, 1600 MeV proton-irradiation experiments (Gilbert et al., 2002), and derive  $^{83}\text{Kr}$  as

73 the most abundant Kr<sub>tr</sub>-isotope, followed by <sup>82</sup>Kr, <sup>81</sup>Kr, <sup>80</sup>Kr, <sup>78</sup>Kr, <sup>84</sup>Kr, <sup>85</sup>Kr and <sup>86</sup>Kr (1 : 0.81 : 0.67 :  
74 0.58 : 0.29 : 0.22 : 0.005 : 0.004; for shielding depth ≥ 49.2 g/cm<sup>2</sup>; Fig. 1).

75  
76 **Fig. 1. Relative abundances of krypton isotopes in natural sources of krypton. Normalized krypton abundances**  
77 **(normalized to the most abundant isotope of a given source) of atmospheric (Aregbe et al., 1996; Sturchio et al.,**  
78 **2004), fissionogenic (from spontaneous fission of <sup>238</sup>U; (Jaea)), nucleogenic (thermal neutron capture by bromine;**  
79 **(Soppera et al., 2014; Kendrick, 2012)), and spallogenic (proton irradiation experiments, zirconium, ≥49 g cm<sup>-2</sup>**  
80 **shielding; Table 2a of Gilbert et al., 2002) krypton. Most geological material on Earth contains atmospheric**  
81 **krypton, with all large geochemical reservoirs (i.e., mantle, crust) containing krypton of atmospheric**  
82 **composition.**

83  
84 The dominant reaction pathway for spallogenic Kr production on zircon appears to be of the type  
85 Zr(n,2α + xn)Kr (with neutron multiplicities x = 0, 1, 2, 3, 4, 5). This may be deduced from (i) the  
86 minimum energies required and (ii) the Zr- and spallogenic Kr-isotope abundances (Gilbert et al.,  
87 2002). At the low energy end (50 MeV (Gilbert et al., 2002)) only α-emissions are possible. This is due  
88 to the energy bonus of the emission of α-particles as compared the emission of individual nucleons,  
89 which is 28.3 MeV per α-particle (1), the separation energies of nucleons (neutrons and protons)  
90 requiring around 8.7 MeV in this mass range (Soppera et al., 2014) and protons additionally requiring >  
91 8 MeV to overcome the Coulomb barrier. The most abundant spallogenic Kr-isotope <sup>83</sup>Kr may be

92 produced on the lightest and most abundant stable Zr-isotope  $^{90}\text{Zr}$  (51.45%) via the energetically  
93 favourable  $(n, 2\alpha)$  reaction, however, also on all other Zr-isotopes via  $(n, 2\alpha + xn)$  reactions ( $x =$   
94 1,2,4,5). Kr-isotopes with masses smaller than 83 require in any case the additional separation of one or  
95 more neutrons, meaning higher minimum energies of the incoming neutrons are needed (Gilbert et al.,  
96 2002), which in turn explains the successively lower production as masses decrease. The lower  
97 production of  $^{84}\text{Kr}$  is commensurate with the lower cumulative abundance of its target nuclides  $^{91,92,94}\text{Zr}$   
98 and, in the case of  $^{92}\text{Zr}$  and  $^{94}\text{Zr}$ , the requirement for the additional separation of one or two neutrons,  
99 respectively. The conspicuous relative rarity of spallogenic  $^{86}\text{Kr}$  (Fig. 1), despite it being the Kr isotope  
100 closest in mass to Zr, probably stems from the fact that there is no  $(n, 2\alpha + xn)$  pathway to produce it on  
101 stable Zr isotopes.

102

### 103 1.2.2 Negative muon capture

104 Muons ( $\mu^-$ ,  $\mu^+$ ), which are products from cosmic ray interactions in the Earth's atmosphere (Dunai, 2010;  
105 Stone et al., 1998) may also contribute to Kr production. Captured negative muons neutralize one proton  
106 and deliver 106 MeV (the mass of a muon at rest) to the nucleus (Dunai, 2010; Stone et al., 1998). Much  
107 of this energy is carried away by neutrino emission ( $\nu_\mu$ ), such that on average close to 20 MeV are  
108 available for nuclear evaporation (Measday, 2001; Lifshitz and Singer, 1980). In the mass range of Zr-  
109 isotopes, captured negative neutrons may induce  $(\mu^-, \nu_\mu + \alpha)$  reactions with probabilities close to  $10^{-4}$   
110 (Wytttenbach et al., 1978). Production of krypton by muon capture on zirconium would require the  
111 separation of one additional charged particle, following reactions of the type  $(\mu^-, \nu_\mu + 2\alpha xn)$  and  $(\mu^-, \nu_\mu +$   
112  $\alpha pxn)$ , with  $x = 0$  to 4. The  $(\mu^-, \nu_\mu + 2\alpha xn)$  reaction would produce a radioactive Br-isotope decaying  
113 into a Kr-isotope. This would work for Kr-isotopes with mass  $\leq 84$ , except for  $^{81}\text{Kr}$  as it is shielded by  
114 stable  $^{81}\text{Br}$ . Using the Coulomb-barrier reaction-probability relationship observed by Wytttenbach et al.  
115 (1978), we estimate that probabilities for  $(\mu^-, \nu_\mu + \alpha p)$  and  $(\mu^-, \nu_\mu + 2\alpha)$  reactions are at least  $10^2$  to  $10^3$   
116 lower than a  $(\mu^-, \nu_\mu + \alpha)$  reaction for a given Zr-isotope. The required separation energy for emission of  
117 one or more neutrons ( $\sim 8.7$  MeV per neutron, see above) would decrease the likelihood of this even  
118 further (Lifshitz and Singer, 1980). Hence, the probability of negative muons captured by Zr-isotopes  
119 producing Kr-isotopes is smaller than  $10^{-6}$ . Of muons coming to rest in zircon,  $35 \pm 4\%$  are captured by  
120 Zr (Von Egidy and Hartmann, 1982) and so the Kr-isotope yield from muon capture by Zr in zircon is  
121 less than 0.3 ppm. This translates into less than  $10^{-6}$  atoms  $\text{g}^{-1} \text{yr}^{-1}$  at sea level and high latitude (Stone et  
122 al., 1998).

123

### 124 1.2.3 Interfering components

125 Geochemical components that may interfere with the analysis of cosmogenic krypton are the products of  
126 spontaneous fission of  $^{238}\text{U}$  (fissionogenic krypton,  $\text{Kr}_{\text{fis}}$ ) and neutron capture by bromine (nucleogenic  
127 krypton,  $\text{Kr}_{\text{nuc}}$ ). These may become important when analysing U- or Br-rich minerals (Eikenberg et al.,

128 1993; Honda et al., 2004; Ruzie-Hamilton et al., 2016; Kendrick, 2012). Fission yields of krypton  
129 isotopes heavier than 81 atomic mass units (AMU) increase with increasing mass such that  $^{86}\text{Kr}_{\text{fis}}$  is the  
130 most abundant, and the yield of  $^{82}\text{Kr}_{\text{fis}}$  is negligible (Fig. 1; (Eikenberg et al., 1993; Jaea)). Spontaneous  
131 fission of  $^{238}\text{U}$  does not produce Kr-isotopes lighter than 82 AMU.  $^{80}\text{Kr}_{\text{nuc}}$  and  $^{82}\text{Kr}_{\text{nuc}}$  may be produced  
132 by reactions on Bromine,  $^{79}\text{Br}(n,\gamma)^{80}\text{Kr}$ ,  $^{81}\text{Br}(n,\gamma)^{82}\text{Kr}$  (reaction cross sections for thermal neutrons are  
133 10.32 and 2.36 barn, respectively (Soppera et al., 2014)). Bromine concentrations are low in silicate  
134 minerals (Kendrick, 2012; Ruzie-Hamilton et al., 2016; Teiber et al., 2015) but commonly not well  
135 constrained. The major geochemical reservoirs of Earth (e.g., mantle) contain krypton close to  
136 atmospheric composition ( $^{80}\text{Kr}$  2.25%;  $^{82}\text{Kr}$  11.6%;  $^{83}\text{Kr}$  11.5%;  $^{84}\text{Kr}$  57.0%;  $^{86}\text{Kr}$  17.3%;  $^{78}\text{Kr}$  0.35%;  
137  $^{81}\text{Kr}$  0.5 ppt; (Buizert et al., 2014; Aregbe et al., 1996)). Natural krypton is rarely measured in geological  
138 material due to the anticipated consistency of these values (Broadley et al., 2020; Trieloff et al., 2000).  
139

#### 140 1.2.4 Test of feasibility

141 To test the feasibility of using  $\text{Kr}_{\text{it}}$  for Earth surface science applications, we analysed a suite of zircon  
142 samples from near-surface sediment and bedrock with a wide range of anticipated exposure histories.  
143 The sediment samples are zircon megacrysts from kimberlitic, carbonatitic and metamorphic source  
144 rocks from locations in Australia (Mud Tank carbonatite; (Crohn and Moore, 1984; Currie et al., 1992)),  
145 Tanzania (Singida kimberlite field and Ubendian-Usagaran metamorphic belt (Mannard, 1962; Kabete et  
146 al., 2012)) and Germany (Ebersbrunn diatreme, Vogtland (Schmidt et al., 2013; Modalek et al., 2009)).  
147 The bedrock samples are from glacially scoured surfaces and a block from the Grimsel Pass,  
148 Switzerland (Wirsig et al., 2016). We use this suite of samples (see section 2 for details) to constrain  
149 terrestrial production ratios of  $\text{Kr}_{\text{it}}$ -isotopes, to cross-calibrate production rates with a well-established  
150 cosmogenic nuclide ( $^{10}\text{Be}$ ), and to provide the first applications by constraining histories of burial and  
151 exposure in arid and temperate regions.  
152

#### 153 2. Sample materials

154 **MUD:** These zircons are from the Mud Tank carbonatite, Northern Territories, Australia (23°0'47"S;  
155 134°16'45"E, 660 m) (32, 33, 83)(Crohn and Moore, 1984; Currie et al., 1992; Gain et al., 2019;  
156 Woodhead and Hergt, 2005). The carbonatite has a crystallization age of  $731.0 \pm 0.2$  Myr (Gain et al.,  
157 2019), protracted cooling or a later thermal overprint during the Alice Springs Orogeny (450–300 Myr)  
158 is indicated by Pb-loss from some zircons (Gain et al., 2019). The emplacement occurred at  
159 temperatures  $\leq 650$  °C, in a fluorine rich environment (Currie et al., 1992). Zircons from this location  
160 have a median HF-concentration of 1.18 % (1st quartile 0.91%, 3rd quartile 1.19% (Woodhead and  
161 Hergt, 2005)). The two carbonatite bodies that constitute this occurrence rise about 10 m above the  
162 surrounding low-gradient landscape (Australian\_Vermiculite\_Industries, 2013). The elevation of  
163 possible sampling locations is  $660 \pm 5$  m.

164 The material used in this study was obtained commercially via a private vendor, as part of two 1 kg  
165 batches of zircon sourced from an estate. The zircons were collected in the 1980s, when zircons were  
166 still abundant at the surface, prior to the Mud Tank becoming a well-frequented mineral collection site  
167 ('fossicking area'; (Australian\_Vermiculite\_Industries, 2013)). The zircons are sub-rounded, some show  
168 percussion marks from fluvial transport and fractured surfaces show signs of subsequent abrasion (Fig.  
169 2). Most have a lighter colour than excavated zircons from the same site (the latter purchased from  
170 Dehne McLauchlin, Tasmania, Australia), suggesting bleaching from extended periods of exposure to  
171 sunlight (Gain et al., 2019). We assume that the zircons analysed were predominantly sampled from the  
172 surface. Individual zircons were crushed using a diamond mortar and subsequently sieved.

173 **SING:** These samples are from the Singida kimberlite field, Tansania (Mannard, 1962). The samples  
174 were obtained commercially (Mawingu Gems, Idar Oberstein, Germany). At least 54 diatremes  
175 (Mannard, 1962) occur in an area of about 1900 km<sup>2</sup> centred around 4°57'S, 34°25'E. The zircon-bearing  
176 kimberlites intruded into the Cretaceous African surface (Mannard, 1962; King, 1978) during the  
177 Eocene (Harrison et al., 2001) at an altitude ranging from 1100 to 1500 m (Harrison et al., 2001). We  
178 adopt an elevation of 1300 m for scaling, when comparing the results from Singida with other locations.  
179 The U-Pb ages of all (n=9) but one of the zircons used in this study are, within their individual  
180 uncertainties, identical to their mean age of  $44.8 \pm 0.2$  Myr ( $\pm 1SD$ ; Table 2). One sample (SING-21)  
181 gives an age of  $40.5 \pm 0.8$  Myr ( $\pm 1SD$ ; Table 2). Remnants of the original tuff-rings are sometimes  
182 preserved (Harrison et al., 2001; Mannard, 1962) so the long-term erosion rates are presumably low.  
183 Much of the area is capped by relict calcretes and silcretes (Mannard, 1962). The area is covered by dry,  
184 deciduous woodland, currently receiving  $520 \pm 260$  mm annual rainfall (Harrison et al., 2001; Mannard,  
185 1962). Zircons are concentrated in river sands near the pipes (Mannard, 1962), where they are mined in  
186 small pits down to several metres depth. We assume such a source for our samples.

187 The individual 5 to 10 mm sized crystals (Fig. 2) are of gem quality. Their outsides show surface  
188 roughing and small percussion marks from fluvial transport. Their Hf-concentrations range between 0.6  
189 and 1.1% (Table 2). Individual zircons were crushed using a diamond mortar and subsequently sieved.

190 **RBM, GOEL & VOGT:** These zircons stem from a kimberlitic diatreme near Ebersbrunn, Vogtland,  
191 Germany (Schmidt et al., 2013; Modalek et al., 2009). Ages of zircons from this location were  
192 determined as  $71.1 \pm 0.8$  Myr (U-Pb; Table 2), which we take as the intrusion age. The diatreme is  
193 located on a topographic saddle (450 m elevation) in a soil-mantled landscape of moderate relief. The  
194 diatreme was first inferred through geophysical surveys and subsequently confirmed via shallow drill  
195 cores (Schmidt et al., 2013).

196 Zircons were obtained from local collectors, either commercially from a private vendor (VOGT) or  
197 provided in exchange (RBM, GOEL; from Sven Kreher, Goldmuseum Buchwald, Germany). They were  
198 extracted from modern stream/river-bed sediments in the Göltzsch near Netschkau (VOGT; GOEL: 300  
199 m, 50°37'25"N, 12°14'47"E), and its tributary Raumbach (RBM: 380 m, 50°37'0"N, 12°21'24"E). The

200 headwaters of the latter originate in the diatrema. The sampling site for RBM zircons is ~ 5 km  
201 downstream of the diatrema, those of VOGT and GOEL ~15 km. The smaller zircons (5-10 mm; all  
202 RBM and GOEL 1, 2 & 3) are mostly transparent, the pebble-sized zircons are opaque to translucent (all  
203 VOGT and GOEL 4 & 5; Fig. 2). Individual zircons were crushed using a diamond mortar and  
204 subsequently sieved.

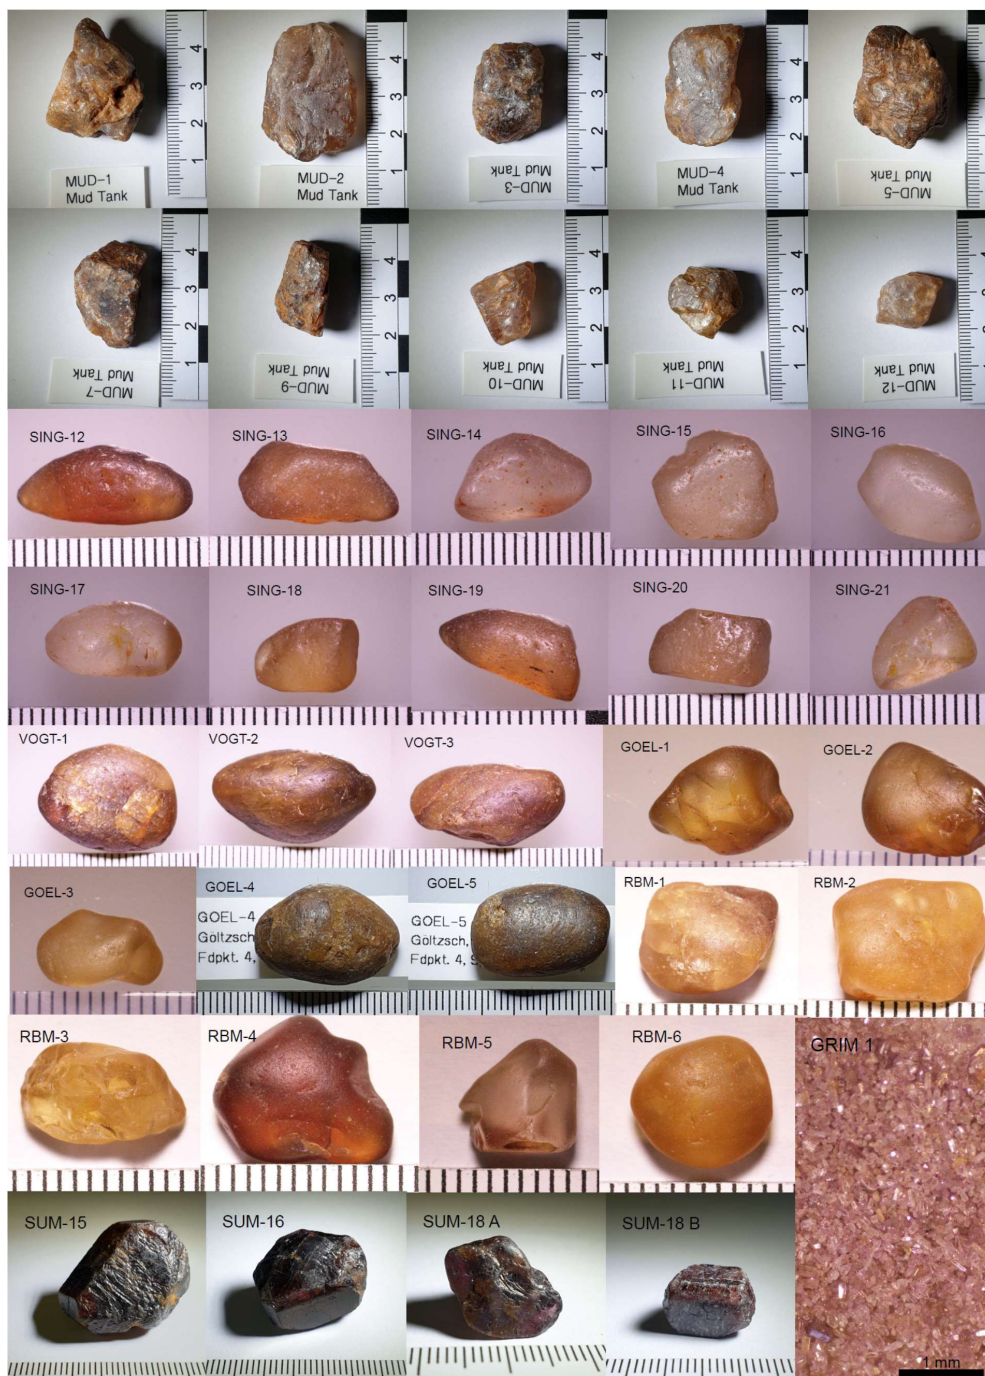

205 **SUM:** These zircons are from the area around Sumbawanga, Tanzania (1850 m, 7°58'S, 31°37'E). The  
206 samples were obtained commercially (Mawingu Gems, Idar Oberstein, Germany). Potential source  
207 rocks are Paleoproterozoic metamorphic rocks (Kabete et al., 2012). We adopt an elevation of 1850 m  
208 for scaling but the actual elevation of the source and/or finding location may be higher. The samples  
209 exhibit signs of fluvial transport such as edge-rounding and percussion marks (Fig. 2). We assume that  
210 these samples were retrieved from stream sediments or sedimentary deposits. The samples are from two  
211 different batches (SUM 18 A & B; the other SUM 15 & 16) and possibly stem from different locations.  
212 Individual zircons were crushed using a diamond mortar and subsequently sieved.

213 **GRIM:** These samples (GRIM 19-1; GRIM 19-2; GRIM -1) are from Nägelisgrätli, east of Grimsel  
214 Pass, Switzerland. The Nägelisgrätli is part of the transfluence pass through which the last-glacial  
215 maximum Aare glacier was fed from the Rhône ice dome (Wirsig et al., 2016). <sup>10</sup>Be concentrations in  
216 quartz-samples from the Nägelisgrätli are consistent with a single stage exposure history, with complete  
217 resetting of signals of prior exposure via glacial erosion (Wirsig et al., 2016). The Grimsel Granodiorite  
218 (part of the Central Aar Granite) has an intrusion age of 298±2Ma (Schaltegger and Corfu, 1992) and  
219 was subsequently affected by regional metamorphism during the Alpine orogenesis around 30–35 Myr  
220 ago (Hettmann et al., 2009).

221 Samples for the current study were taken at 2390 m (GRIM 19-1: 46°33'57.66"N, 8°20'46.57"E; GRIM  
222 19-2: 46°33'57.58"N, 8°20'46.71"E) and 2478 m (GRIM-1: 46°34'13.9"N, 8°21'6.4"E) elevation.

223 GRIM-1 and GRIM 19-1 are bedrock samples (Fig. 3). GRIM 19-2 a loose block in a shallow  
224 depression (Fig. 3) and was presumably ice-transported to this location, as all other means of transport,  
225 such as falling or rolling from uphill, can be excluded. The topography in the immediate vicinity of the  
226 sampling sites is favourable for accumulating significant snow cover (significant in terms of capability  
227 to reduce cosmogenic nuclide production). We performed no snow-cover corrections, since the main  
228 purpose of these samples is to cross-calibrate production rates of cosmogenic nuclides that are equally  
229 affected by snow-cover, i.e., snow-cover effects cancel each other out. The same applies to topographic  
230 shielding corrections, which we likewise did not apply. Electro pulse disaggregation of samples and  
231 subsequent zircon separation, by standard magnetic and heavy liquid techniques, was conducted by  
232 Zirchron LLC, Tucson, Arizona, USA. The zircon grains are < 125 microns (Fig. 2).

233

234

235

**Figure 2: Photos of the zircons investigated. Scales are mm and cm. GRIM-1 is exemplary also for samples GRIM 19-1 and GRIM 19-2 (not shown). Crystals' weights are provided in Table 1 (where applicable).**

## 242 3 Methods

### 243 3.1 Krypton isotope determinations

244 The general layout of the noble gas set-up at Cologne is described in Ritter et al. (2021), who focus on  
245 the analysis of cosmogenic neon. Here we reproduce some aspects of this description (Ritter et al.,  
246 2021), adding details that are pertinent for Kr-extraction from zircon and cosmogenic Kr-analysis.

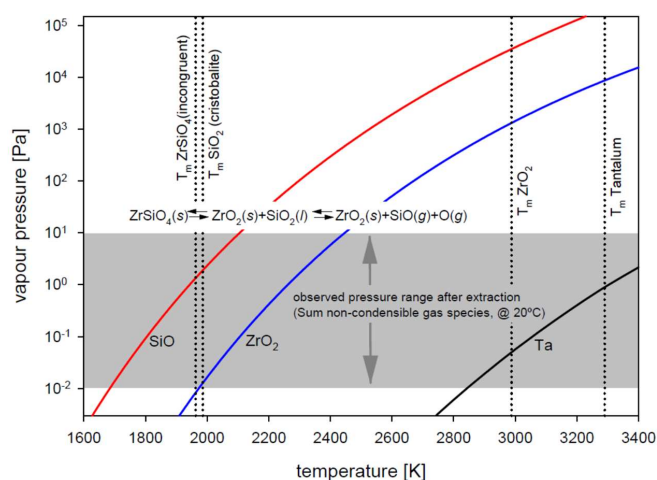

247

#### 248 3.1.1 Krypton extraction from zircon

249 Samples are placed into tantalum tubes (4 mm outer diameter, ca. 12 mm long) that are pinched off at  
250 both ends. The tantalum tubes are placed into tungsten cups, which in turn are placed into a  
251 molybdenum sample revolver. For thermal insulation, several fragments (250-500 micron) of zirconia  
252 (cubic stabilized zirconium oxide, melting point  $\sim 2700^{\circ}\text{C}$ ) are placed between the cups and revolver.  
253 Energy for the heat-extraction in vacuum is provided by an output-tuneable 600 W fiberlaser (Rofin  
254 StarFiber600) at 1064nm wavelength through galvanometer scanner optics (Rofin RS S 14 163/67 0°), a  
255 UV-grade fused silica viewport (MDC Precision, 9722005) and a single-use fused-silica protective glass  
256 (Thorlabs, WG41050). The tantalum-tubes are heated via scanning a continuous wave beam with 200W  
257 power for a total of five minutes. The scanning speed is 20 cm/s; first rastering a rectangular area of 4 by  
258 10 mm with a defocused beam ( $\sim 0.5$  mm diameter) for three minutes, then with focussed beam a  
259 circular area with 5 mm diameter, on the then shrivelled tube, for two minutes. The temperature  
260 achieved is sufficient to melt the top of the Tantalum tube (melting point of Tantalum is  $3020 \pm 15^{\circ}\text{C}$ ;  
261 (Arblaster, 2018)) and to quantitatively sublime the silica content of zircon. Zircon melts

262 incongruently above  $\sim 1690^\circ\text{C}$  (Kaiser et al., 2008) and the silica is presumably lost as silicon monoxide  
263 and oxygen (Fig. 4; Schick, 1960). Silicon monoxide is observed as brown coating on the protection  
264 windows; the coating starts to appear within about one minute after starting the laser extraction. The  
265 quantitative loss of silica is verified by weighing of the tantalum tubes after heat-extraction; in most  
266 cases, the measured loss indicates also partial sublimation of  $\text{ZrO}_2$  (Fig. 5; Hoch et al., 1954).  
267

268  
269 **Figure 4: Vapour pressure of Silicon monoxide (SiO), zirconia ( $\text{ZrO}_2$ ) and tantalum (Ta) as a function of**  
270 **temperature (Schick, 1960; Hoch et al., 1954; Arblaster, 2018; Kaiser et al., 2008), and the melting points of**  
271 **zircon ( $\text{ZrSiO}_4$ ), cristobalite ( $\text{SiO}_2$ ) and zirconia (Kaiser et al., 2008). Zircon melts incongruently to  $\text{ZrO}_2$  and**  
272  **$\text{SiO}_2$ -melt (the melting temperature of the high-temperature modification of  $\text{SiO}_2$ , cristobalite, is only  $\sim 10\text{K}$**   
273 **higher than that of zircon) (Kaiser et al., 2008). At a given temperature the vapour pressure of SiO is one to two**  
274 **orders of magnitude higher than that of  $\text{ZrO}_2$ , the larger differences are at lower temperatures. Above the**  
275 **melting point of cristobalite, SiO can boil off, rather than sublimate from the surface of a solid (as is the case**  
276 **for  $\text{ZrO}_2$ , below its melting point), if the pressure in the extraction cell is lower than the vapour pressure.**  
277 **Observations of the residual pressure of non-condensable gases after extraction (at this time the laser furnace is**  
278 **still hot from the extraction, but the laser power is switched off) indicate that in our experimental setup SiO may**  
279 **boil off at temperatures  $> 2100\text{K}$ . The higher vapour pressure and the ability to boil off from a liquid leads to a**  
280 **preferential loss of SiO, as compared to  $\text{ZrO}_2$ , from zircon at high temperatures.**

281

282 *Figure 5: Relative mass loss of zircon samples after laser extraction as a function of initial sample weight.*  
283 *Squares denote samples with grain sizes above 125 μm, circles denote samples that (also) contain grains smaller*  
284 *125 μm. All but one sample (RBM-6) have completely lost their constituent SiO<sub>2</sub> and some of the ZrO<sub>2</sub> residue*  
285 *(see also Fig. 4).*

286

### 287 3.1.2 Krypton isotope determination

288 Subsequent to the extraction, the evolved gases cleaned by sequential exposure to two reactive metal  
289 getters (SAES NP50) and a stainless steel watertrap (held at 205 K). The noble gases are separated  
290 cryogenically on a stainless steel coldtrap (Janis, twin coldhead model 204): neon and heavier noble  
291 gases are quantitatively condensed on the trap at 24 K; the trap is then heated to 120 K and pumped (neon  
292 and argon are removed; >99% of Kr remains on the trap); finally, the trap is heated to 240 K to release  
293 Kr for analysis in a noble gas mass spectrometer.

294

295 The noble gas mass spectrometer (Helix MCPlus, Thermo Fisher Scientific) is equipped with five  
296 Combined Faraday Multiplier modules (CFM). One CFM is fixed in axial position (Ax) and two  
297 movable CFM are each on the low (L1, L2) and the high (H1, H2) mass side of Ax. The L1 CFM is  
298 flipped as compared to the factory-standard configuration (lateral positions of multiplier and faraday  
299 slits are swapped). Four Faraday collectors are fitted with  $10^{13} \Omega$  pre-amplification resistors (H1, Ax,  
300 L1, L2), one with  $10^{12} \Omega$  (H2). The multipliers are operated in ion-counting mode. One CFM module  
301 (L1 position) has a higher resolution (0.3 mm entry slit), the others have regular resolution (0.6 mm  
302 slits). At the operation conditions we used for krypton analysis (source slit 0.25 mm; 10 KV acceleration  
303 voltage), mass resolution (at 5% peak valley) and mass resolving power (between 10% and 90% of  
304 peak) on the L1 detector with 0.3 mm collector slit width are ~1700 and ~6500, respectively. For the  
305 detectors with 0.6 mm collector slit, the corresponding values are ~1000 and ~6000, respectively. This  
306 resolution allows the full separation of krypton isotopes from hydrocarbon isobars (~600 is required;  
307 Burnard et al., 2013). The resolution of the L1 detector achieves separation of  $^{40}\text{Ar}_2\text{H}^+$  from  $^{81}\text{Kr}^+$  at

308  $^{81}\text{Kr}^+$ -peak centre. Partial resolution is achieved on the remaining detectors, permitting interference-free  
309 ( $^{40}\text{Ar}_2\text{H}^+$ ) analysis of  $^{81}\text{Kr}^+$  in an off-centre position. Interference of  $^{80}\text{KrH}^+$  on  $^{81}\text{Kr}^+$  cannot be resolved;  
310 we determine the  $^{84}\text{KrH}^+/^{84}\text{Kr}^+$ -ratio during calibration gas measurements (observed range  $2 - 5 \times 10^{-6}$ ;  
311  $n=26$ ) as a proxy for the  $^{80}\text{KrH}^+/^{80}\text{Kr}^+$ -ratio and correct sample signals accordingly. Likewise, the  
312 interference from  $^{81}\text{Br}^+$  cannot be resolved, we corrected it via monitoring and subtracting the  
313 background at the position of  $^{81}\text{Kr}^+$  during blank measurements. This background was found to be stable  
314 at the equivalent of  $2200 \pm 200$  ( $n=7$ ; 1SD) atoms  $^{81}\text{Kr}$ . Using multiples ( $m$ ) of the blank value ( $2200 \pm$   
315  $200$  atoms), we estimate the detection limit for  $^{81}\text{Kr}$  with the current setup is  $\sim 7000$  atoms ( $m=3$ ).  
316 Blanks yield  $0.65 \pm 0.30$  attomol  $^{84}\text{Kr}$  ( $n=8$ ). Measurements of hot blanks  $0.75 \pm 0.25$  attomol  $^{84}\text{Kr}$  (hot  
317 laser extraction,  $n=5$ , 1SD of mean), cold blanks  $0.55 \pm 0.05$  attomol  $^{84}\text{Kr}$  (same volume, but laser power  
318 off,  $n=2$ , 1SD of mean), or the line blank  $0.5 \pm 0.1$  attomol  $^{84}\text{Kr}$  (purification line only, without the laser  
319 extraction volume,  $n=1$ , 1SD of measurement) are indistinguishable from each other. The observed Kr-  
320 blanks are about four-times lower than the lowest reported previously (Zimmermann et al., 2018).

321

322 We analysed the krypton isotopic abundances in multicollection mode. First, masses 78 to 85 are  
323 measured in four cycles on the multipliers; 1st:  $^{84}\text{Kr}(\text{H}2)$ ,  $^{83}\text{Kr}(\text{H}1)$ ,  $^{81}\text{Kr}(\text{Ax})$ ,  $^{80}\text{Kr}(\text{L}1)$ ,  $^{78}\text{Kr}(\text{L}2)$ ; 2nd:  
324  $^{83}\text{Kr}(\text{H}2)$ ,  $^{82}\text{Kr}(\text{H}1)$ ; 3rd:  $^{82}\text{Kr}(\text{Ax})$ ,  $^{81}\text{Kr}(\text{L}1)$ ; 4th:  $^{84}\text{KrH}^+(\text{H}2)$ ,  $^{84}\text{Kr}(\text{H}1)$ , followed by sequential analysis  
325 of masses 86, 84, 83 and 82 on the axial Faraday cup. Gain calibrations of multipliers are performed  
326 relative to the H1 multiplier, using the measurements of calibration gas (air-pipette, containing  
327  $11.25 \pm 0.01$  fmol Kr) and the isotopic composition of air (Aregbe et al., 1996). The gain of the H1  
328 multiplier is in turn calibrated to the axial Faraday collector using the corresponding  $^{84}\text{Kr}^+$  readings of  
329 calibration gas measurements. Within each of the two measurement periods, the variability of  $^{84}\text{Kr}$   
330 Faraday signals for calibration gas were smaller than  $\pm 1\%$  (1 SD,  $n=26$ ). Between the two periods the  
331 ion source was switched off and after turning the source back on the sensitivity had dropped by 4%.  
332 Calibration gas was measured prior to a set of two or three sample measurements on a given day, with  
333 these preceding calibrations used for gain calibration and interference correction ( $^{80}\text{KrH}^+$ ) of the  
334 subsequent samples. We use both determinations of  $^{81}\text{Kr}$ , on Ax (off-centre) and on L1, to obtain an  
335 error weighted mean of intensities. We calculate the concentration of  $^{78}\text{Kr}_{\text{it}}$  from the measured  $^{78}\text{Kr}/^{82}\text{Kr}$   
336 ratio, assuming that all  $^{82}\text{Kr}$  is atmospheric. The  $^{81}\text{Kr}_{\text{it}}$  concentration is corrected for interferences ( $^{81}\text{Br}^+$ ,  
337  $^{80}\text{KrH}^+$ ).

338

### 339 3.2 $^{10}\text{Be}$ determination

340 Samples were ground and sieved to 250-1000  $\mu\text{m}$  and subsequently purified through sequential HF-  
341 leaching (Kohl and Nishiizumi, 1992). ICP-OES was used to verify the purity of the quartz before  
342 dissolution.  $^{10}\text{Be}$  AMS (Accelerator Mass Spectrometry) targets were prepared using the stacked column  
343 approach (Binnie et al., 2015). A reagent blank and in-house quartz reference material (CoQtz-N;

344 (Binnie et al., 2019)) was prepared in tandem with the samples. AMS measurements were made on  
345 CologneAMS (Dewald et al., 2013), normalized to the ICN standard dilutions prepared by Nishiizumi  
346 for  $^{10}\text{Be}$  (Nishiizumi et al., 2007). Concentrations of  $^{10}\text{Be}$  are reported following blank subtractions,  
347 which were less than 1% of the total number of nuclides measured. The 1 standard deviation analytical  
348 precision of the nuclide concentrations was estimated by summing in quadrature the relative  
349 uncertainties on the AMS measurements, both the samples and the blank, along with a 1% (1 SD)  
350 estimate for the precision of the mass of  $^9\text{Be}$  added during spiking. Concentrations obtained from  
351 intercomparison material (CoQtz-N; (Binnie et al., 2019)) measured alongside the samples are  
352 consistent with the long-term arithmetic mean  $2.43 \pm 0.11 \times 10^6$  atoms  $\text{g}^{-1}$  CoQtz (1SD;  $N = 55$ ) at our  
353 laboratory.

354

### 355 **3.3 U-Pb-age determination**

356 U, Th and Pb isotopes of zircon were performed by LA-ICPMS at FIERCE (Frankfurt Element and  
357 Isotope Research Center), Goethe University Frankfurt following the methods described in Gerdes et al.  
358 (2009). A Thermo Scientific Element XR sector field ICP-MS was coupled to a RESOLUTION 193 nm  
359 ArF Excimer laser (Compex Pro 102, Coherent) equipped with an S-155 two-volume ablation cell  
360 (Laurin Technic, Australia). The GJ-1 zircon ( $603 \pm 1$  Myr) was used as primary zircon reference  
361 material (RM) and RMs BB-16, Plešovice and Monastery zircon for validation of the analytical results.  
362 The results obtained on these zircon RMs were within 0.8% or better of the reported ages. Data  
363 processing (including common lead correction) was performed using an Isoplot (Ludwig, 2012)-  
364 supported Microsoft Excel-based spreadsheet (Gerdes and Zeh, 2009). Uncertainties reported are at the  
365 2SD level (i.e. 95% confidence) and are calculated by quadratic addition of the internal uncertainties  
366 (SE), counting statistics, gas-background uncertainties, common Pb corrections, the excess of scatter  
367 derived from the primary RM.

368

### 369 **4 Results**

370 The results of the, Kr-isotope determinations, U-Pb age-determinations, and the  $^{10}\text{Be}$ -results are  
371 provided in Tables 1, 2 and 3, respectively.

#### 395 4.1 Proof of concept for in situ produced terrestrial krypton

396

397

398

399

400

401

402

403

404

We find that all zircons analysed have <sup>78</sup>Kr/<sup>82</sup>Kr and/or <sup>80</sup>Kr/<sup>82</sup>Kr-ratios that are distinct from air (Fig. 6) and that the majority of samples form a trend that follows a hypothetical mixing line between air (Aregbe et al., 1996) and a spallogenic endmember (Gilabert et al., 2002) (Fig. 6). Neither mass-fractionation nor the addition of nucleogenic <sup>80</sup>Kr and/or <sup>82</sup>Kr can produce the main trend (Fig. 6). However, either process may account for samples deviating from the mixing line. Furthermore, all zircons contain quantifiable amounts of <sup>81</sup>Kr (Fig. 7) that, in the absence of alternative sources, must be cosmogenic. Both observations, the mixing array and the presence of <sup>81</sup>Kr demonstrate the feasibility of measuring Kr<sub>tr</sub> in terrestrial material.

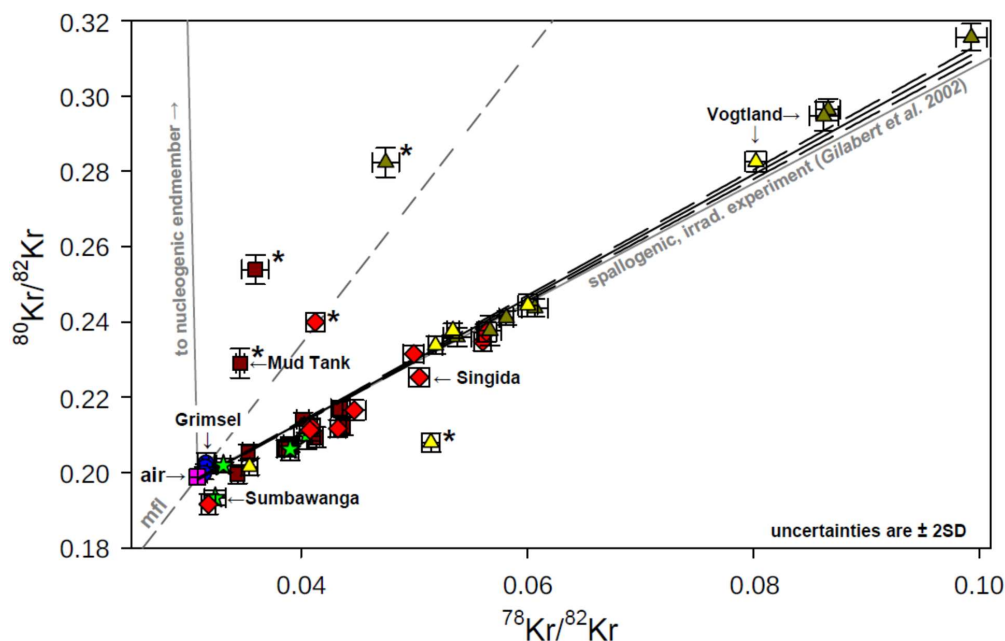

405 Mass fractionation of noble gases is a common feature for samples originating from degassing magmatic  
406 systems (Kaneoka, 1980). Samples may contain residual gas from diffusive loss (enriched in heavy  
407 isotopes), or trapped gas that was fractionated during diffusion from minerals and/or degassing from  
408 melts (enriched in light isotopes). The resulting mass fractionation causes samples to plot along a path  
409 that deviates from the spallation line (Fig. 6). The samples that lie above the spallation line and to the  
410 left of the mass fractionation line (two from Mud Tank, one each from Singida and Vogtland) must  
411 contain some nucleogenic Kr; requiring bromine in the host rocks, their sources, and/or the samples  
412 themselves. Structurally there is no suitable site for bromine in the zircon lattice, so if present it is  
413 trapped in fluid or melt inclusions. Sources for kimberlites appear to be rich in halogens and in bromine  
414 (Kamenetsky et al., 2014; Burgess et al., 2009), which could explain the presence of nucleogenic Kr in  
415 some Singida and Vogtland zircons. The original melt, or source, of the Mud Tank carbonatite was rich  
416 in halogens (Currie et al., 1992), presumably containing sufficient bromine to give rise to significant  
417 nucleogenic Kr. Fractionation and the presence of nucleogenic Kr are interesting on their own account;  
418 to our knowledge natural nucleogenic Kr has not been reported before. However, for the purpose of the  
419 present study, we limit the use of the Krypton triple-isotope plot (Fig. 6) to discern samples with a  
420 simple  $Kr_{atm}$  and  $Kr_{it}$  mixture from those with complex components.

421

#### 422 **4.2 Production ratios of terrestrial cosmogenic krypton isotopes**

423 In detail, the atmospheric - spallogenic mixing trend in  $^{78}Kr/^{82}Kr$ - $^{80}Kr/^{82}Kr$  space (Fig. 6) that is defined  
424 by our results is slightly steeper than the one inferred from the proton-irradiation experiments (Gilbert  
425 et al., 2002) (zircon data:  $1.682 \pm 0.015$  (1SD) vs. proton irradiation  $\geq 49.2$  g cm<sup>-2</sup> shielding:  $1.592 \pm 0.020$   
426 (1SD); Fig. 6). Hence, the  $^{78}Kr/^{82}Kr$  and/or  $^{80}Kr/^{82}Kr$  production ratios appear to be different by ~4% in  
427 the zircons as compared to the irradiation experiment. This small difference is unsurprising considering  
428 that in the proton irradiation experiments the 1600 MeV primary proton beam, as well as secondary  
429 protons and neutrons, produce Kr-isotopes in roughly similar proportions (Gilbert et al., 2002), whereas  
430 near the Earth surface secondary neutrons dominate (~90% at sea level (Dunai, 2010)). We take the  
431 good agreement as indication that in the mass range of  $^{78}Kr$  to  $^{82}Kr$  the isotopic production ratios derived  
432 from proton-irradiation experiments (Gilbert et al., 2002) are a reasonable approximation for Kr  
433 produced by spallation on Zr near the Earth's surface.

434

435

436 *Fig. 6. Identification of krypton components and of processes fractionating krypton isotopes. Kr-data from*  
 437 *zircons of various locations, all of which have been exposed to cosmic rays at or near the Earth's surface, form*  
 438 *a linear trend between air (atmospheric Kr; (Aregbe et al., 1996)) and a spallogenic endmember. Several*  
 439 *samples plot far from this trend (marked with an asterisk \*). They may contain fractionated Krypton ('mfl'*  
 440 *mass-fractionation line; (Kaneoka, 1980)) and/or nucleogenic krypton. The regression of the data (performed*  
 441 *with regression module of SigmaPlot 14) is shown by the solid black line and excludes measurements marked*  
 442 *with an asterisk \*. The regression is forced through air. The black dashed lines are the 95% confidence*  
 443 *intervals of the regression line. Regression of the Kr concentrations from the zircon samples indicates that the*  
 444 *terrestrial cosmogenic endmember is slightly different to that obtained from proton irradiation experiments*  
 445 *(solid grey line; (Gilbert et al., 2002)). Brown squares are Mud Tank carbonatite; red diamonds are for the*  
 446 *Singida kimberlite field; green stars are Sumbawanga; blue circles are the Grimsel pass region; triangles*  
 447 *represent Vogtland (dark yellow: samples GOEL & VOGT; yellow: samples RBM).*

448

#### 449 4.3 Cross-calibration of $^{81}\text{Kr}$ and $^{10}\text{Be}$ production rates

450 In samples of glacially eroded rocks from the Grimsel Pass (Switzerland) we determined concentrations  
 451 of both  $^{81}\text{Kr}_{\text{it}}$  in zircon and  $^{10}\text{Be}$  in quartz (Tables 1 & 3). The resulting  $^{81}\text{Kr}_{\text{it}}(\text{zrc})/^{10}\text{Be}(\text{qtz})$  ratio is  
 452  $1.545 \pm 0.045$  (1SE, error weighted mean,  $n=3$ ). Using a  $^{10}\text{Be}$  production rate of  $4.10 \pm 0.17$  atoms  $\text{g}^{-1} \text{yr}^{-1}$   
 453 (1SE; at sea level and high latitude (SLHL) for Europe (Martin et al., 2017); LSD scaling (Lifton et al.,  
 454 2014), atmospheric pressure (Uppala et al., 2005)), we derive a SLHL  $^{81}\text{Kr}_{\text{it}}$  production rate of  
 455  $6.33 \pm 0.32$  atoms  $\text{g}^{-1} \text{yr}^{-1}$  (1SD) in zircon.

456

#### 457 **4.4 Histories of exposure and burial**

458 Due to decay of  $^{81}\text{Kr}$ , intermittent burial of samples lowers the measured  $^{81}\text{Kr}/^{78}\text{Kr}_{\text{it}}$  ratio with respect to  
459 the production ratio; with increasing exposure time at the surface, the measured  $^{81}\text{Kr}/^{78}\text{Kr}_{\text{it}}$  -ratio  
460 decreases as  $^{81}\text{Kr}$  tends towards saturation concentrations. Hence, samples with the highest  $^{81}\text{Kr}/^{78}\text{Kr}_{\text{it}}$  -  
461 ratio for a given  $^{81}\text{Kr}$  concentration ( $^{81}\text{Kr}$  concentration is a proxy for the duration of exposure; Fig. 7)  
462 may be used to constrain the  $^{81}\text{Kr}/^{78}\text{Kr}_{\text{it}}$  production ratio. Using the two samples from Mud Tank with  
463 the highest  $^{81}\text{Kr}/^{78}\text{Kr}_{\text{it}}$  ratio for exposures >200 kyr (MUD-1 & MUD-11), we constrain the  $^{81}\text{Kr}/^{78}\text{Kr}_{\text{it}}$   
464 production ratio to be  $1.94 \pm 0.09$  (1 SE; error weighted mean). The  $^{81}\text{Kr}/^{78}\text{Kr}_{\text{it}}$  production ratio derived  
465 from proton irradiation experiments is ~15% higher (for  $\geq 49.2 \text{ g cm}^{-2}$  shielding,  $^{81}\text{Kr}/^{78}\text{Kr}_{\text{it}} = 2.30 \pm 0.02$ ,  
466 1SD; Table 2a of Gilabert et al. 2002). This difference may be due to unaccounted for episodes of  
467 sample burial, or the inherently different reaction pathways and energy spectra in proton experiments  
468 (Gilabert et al., 2002) as compared to the secondary neutron flux at the Earth's Surface (Lifton et al.,  
469 2014). Using either production ratio, the results for all Mud Tank zircons analysed are consistent with  
470 the  $^{81}\text{Kr}_{\text{it}}$  production rate of  $6.33 \pm 0.32 \text{ atoms g}^{-1} \text{ yr}^{-1}$  derived earlier and the  $^{81}\text{Kr}$  half-life of  $229 \pm 11 \text{ kyr}$   
471 (Baglin, 2008), assuming either a continuous exposure, a uniform erosion rate, or a complex exposure  
472 history (Fig. 7). In the following we use the  $^{81}\text{Kr}/^{78}\text{Kr}_{\text{it}}$  production ratio of  $1.94 \pm 0.09$ .

473

#### 474 **4.4.1 Glacially exhumed samples**

475 The results of the glacially exhumed samples from the Grimsel Pass area are consistent with a post-  
476 LGM (Last Glacial Maximum) exposure under a variable and significant snow cover (Wirsig et al.,  
477 2016). Grimsel Pass  $^{81}\text{Kr}/^{78}\text{Kr}_{\text{it}}$  values (Fig. 7) are consistent with the production ratio derived from the  
478 Mud Tank zircons within two standard deviations (1.94; see above), however, two of three samples are  
479 inconsistent with the experimental value (2.3, see above). Irrespective of eventual intermittent cover,  
480 samples with no exposure prior to glacial erosion history (as is inferred for Grimsel Pass area, see  
481 section 2) should exhibit  $^{81}\text{Kr}/^{78}\text{Kr}_{\text{it}}$ -ratios indistinguishable from the production ratio. The difference  
482 between the expected  $^{81}\text{Kr}_{\text{it}}$  concentrations at Grimsel Pass (commensurate to ~13 kyr exposure (Wirsig  
483 et al., 2016)) and those measured (Fig. 7) indicate a notable amount of seasonal snow cover at our  
484 sampling locations (Wirsig et al., 2016). The quartz-vein samples used by Wirsig et al. (2016) for  
485 exposure dating were collected on steep-sided outcrops to prevent significant snow-cover; our granite  
486 samples were from near-horizontal outcrops (Fig. 3) to ensure a simple exposure geometry of our large  
487 (~10 kg; in order to recover sufficient zircon) and thick samples (10 to 15 cm).

488

489

490

491  
 492 *Fig. 7. Unravelling histories of exposure and burial. In a  $^{81}\text{Kr}/^{78}\text{Kr}_{\text{fit}}$  vs.  $^{81}\text{Kr}$  two-isotope plot, analogous to*  
 493 *similar diagrams used for  $^{26}\text{Al}$  and  $^{10}\text{Be}$  (Dunai, 2010; Lal, 1991) or  $^{21}\text{Ne}$  and  $^{10}\text{Be}$  (Kober et al., 2009), histories*  
 494 *of exposure and burial can be deciphered. The spallogenic  $^{81}\text{Kr}/^{78}\text{Kr}_{\text{fit}}$  production ratio ( $1.94 \pm 0.09$ ; 1SE*  
 495 *calculated from samples MUD-1 & MUD-11; see main text), the  $^{81}\text{Kr}_{\text{fit}}$  production rate ( $6.33 \pm 0.32 \text{ atoms g}^{-1}\text{yr}^{-1}$ ;*  
 496 *this study) and the  $^{81}\text{Kr}$  half-life ( $229 \pm 11 \text{ kyr}$  (Baglin, 2008)) are used to define the boundaries between*  
 497 *areas that are forbidden (no physically plausible explanation), areas that denote simple continuous exposure or*  
 498 *steady state erosion, or complex histories that include intermittent burial. Samples that are continuously*  
 499 *exposed at the surface may be used to test the consistency of the  $^{81}\text{Kr}/^{78}\text{Kr}_{\text{fit}}$  production ratio and/or  $^{81}\text{Kr}_{\text{fit}}$*   
 500 *production rate applied. Due to the decay of  $^{81}\text{Kr}$ , the  $^{81}\text{Kr}/^{78}\text{Kr}_{\text{fit}}$  ratio of exposed samples decreases with*  
 501 *increasing exposure age until the  $^{81}\text{Kr}$  concentration eventually saturates (production rate = decay rate) after*  
 502 *about 8 - 9 half-lives (this limit is dependent on the analytical uncertainties achieved). For exposures > 1 Myr,*  
 503 *the  $^{81}\text{Kr}_{\text{fit}}/^{78}\text{Kr}_{\text{fit}}$  ratio is a direct proxy for the exposure age (Marti, 1967), independent of scaling factors or*  
 504 *shielding as long as the latter is constant through time (Marti, 1967). Upon burial the previously acquired  $^{81}\text{Kr}_{\text{fit}}$*   
 505 *inventory decays over time, allowing, in the case of a single period of deep burial, its duration to be determined.*  
 506 *All samples are consistent with either continuous exposure at the Earth's surface, exhumation at a steady rate,*  
 507 *or with histories that include burial after exposure ('complex exposure'). Samples marked with an asterisk (\*)*  
 508 *are those that were identified to contain fractionated and/or nucleogenic Kr (Fig. 6); results of these samples*  
 509 *are excluded from further evaluation. The two colours used for the samples from Vogtland denote the distance*  
 510 *they were collected downstream of their source (yellow ~5 km; dark yellow ~15 km). Symbols and colours for*

511 *samples are the same as in Figure 6. For two samples from Grimsel (GRIM-19-1 & 2) the error weighted means*  
512 *(ISE) of duplicate/triplicate measurements are plotted. The  $^{81}\text{Kr}_i$  concentrations are normalized to sea-level and*  
513 *high-latitude using LSD scaling (Lifton et al., 2014), and the standard atmosphere model to convert altitude*  
514 *into atmospheric pressure (Balco et al., 2008). The evolution trajectories shown are calculated using a*  
515  *$^{81}\text{Kr}_i/^{78}\text{Kr}_i$  production ratio of 1.94 (this study), a sea-level high-latitude  $^{81}\text{Kr}_i$  production rate of 6.33 (this*  
516 *study), the  $^{81}\text{Kr}_i$  half-life of 229 kyr (Baglin, 2008), and a density of  $2.7 \text{ g cm}^{-3}$  for source rocks and/or*  
517 *overburden. Format of diagram after Lal (1991). The two, subordinate, steady-state erosion islands bound by*  
518 *the grey lines give hypothetical examples of where samples would plot had they been originally exposed at the*  
519 *surface and then buried at a significant depth for 500 kyr, or for 1 Myr. The two sets of example production*  
520 *trajectories illustrate regrowth at shallower depths (i.e., 3 m, 2 m, 1 m and 0.5 m; during 500 and 1000 kyr of*  
521 *burial, respectively). Trajectories are vertically offset within each set for better visibility (i.e., the trajectories for*  
522 *the different burial depths actually originate from one point). Dots on the regrowth trajectories are for 0 yr, 10*  
523 *kyr, 50 kyr, 100 kyr, 500 kyr, and 1 Myr production, respectively.*

524

#### 525 4.4.2 Sedimentary samples

526 The sedimentary zircon megacrysts from Australia, Tanzania and Germany have the ability to record  
527 their individual (paleo-) exhumation and subsequent burial histories. Their exhumation rate is taken to  
528 be representative of the erosion rates of their former host rocks (for simplicity we assume a  $2.7 \text{ g cm}^{-3}$   
529 density for all, which may not necessarily be the case). The simplest case is for zircons from Mud Tank  
530 (Australia), since they were collected at or near the surface in close proximity to their source rock. The  
531 sample results indicate individual exhumation rates between  $1 \text{ m Myr}^{-1}$  and  $0.1 \text{ m Myr}^{-1}$  and that some  
532 zircons have had a complex exposure history, with intermittent burial and/or production at shallow  
533 depths. These results are consistent with erosion rates obtained for other low-relief, post-orogenic  
534 landscapes in arid Central Australia (Struck et al., 2018b; Struck et al., 2018a) and with being sampled  
535 at or near the surface of a thin sediment cover (Australian\_Vermiculite\_Industries, 2013; Struck et al.,  
536 2018a).

537

538 A more complex history is implied for the zircons from the Singida peneplain (Tanzania, Mannard,  
539 1962). The sediments of the ephemeral rivers from which they were mined commonly have a thickness  
540 of several meters; thus, samples may record extended periods of burial. The samples from the Singida  
541 form a pattern ( $n=9$ ; Fig. 7) that is commensurate with exhumation rates lower than  $0.1 \text{ m Myr}^{-1}$  and  
542 continuous exposure at the surface, or burial for to up to 1 Myr. These results from the Singida diatreme  
543 field are consistent with expectations for an arid, low-relief ( $<50 \text{ m}$ ), long wavelength ( $> 10 \text{ km}$ )  
544 landscape (Mannard, 1962; Harrison et al., 2001), notionally a relic of Cretaceous age ('African Surface';  
545 Mannard, 1962; King, 1978; Burke et al., 2008). The notion of long-term low erosion rates is supported  
546 by the partial preservation of tuff-rings of Eocene diatremes (Mannard, 1962; Harrison et al., 2001),  
547 with the tuffs being the source-rocks of the zircons (Mannard, 1962). The erosion rates we infer from the  
548 zircons are very low ( $< 0.1 \text{ m Myr}^{-1}$ ), and appear to have been invariable during the last 1 Myr.

549 Assuming these rates apply to even longer time scales, the source of the zircons would have eroded by  
550 less than 4.5 m since the eruption of the diatreme,  $44.8 \pm 0.2$  Myr ago (mean U-Pb ages of zircons;  $n=9$ ,  
551 1SD; Table 2).

552

553 The basic framework for Zircons from Sumbawanga (Tanzania) is similar to Singida inasmuch as the  
554 zircons were retrieved from river sediments but the surface process rates are different. The Precambrian  
555 source rocks (Kabete et al., 2012) for zircons from Sumbawanga have experienced post Mid-Miocene  
556 uplift and tectonic segmentation as part of the Tanganyika–Rukwa–Malawi transform-segment of the  
557 East African Rift segments (Chorowicz, 2005). The resulting localized, short wavelength (1-8 km) relief  
558 is in places significant (up to 600m). The current local climate is temperate (Peel et al., 2007), rather  
559 than arid. The samples from Sumbawanga (Fig. 7) indicate individual exhumation rates around 1 m  
560  $\text{Myr}^{-1}$  and all but one have had a complex exposure history, with burial for up to 500 kyr and/or  
561 production at shallow depths. The order of magnitude higher erosion rates inferred for source regions of  
562 Sumbawanga zircons, as compared to Singida, are commensurate with the different tectonomorphology  
563 and climatic conditions.

564

565 The setting of the samples from the Vogtland (Germany) is distinct from the other sedimentary samples  
566 in this study as it is the only location that experienced periglacial conditions in the past (Eissmann,  
567 2002). The area was never glaciated but was within 50 km of the ice-margins during the largest  
568 Quaternary glaciations (Eissmann, 2002). The climate is currently temperate (Bohn and Gollub, 2006;  
569 Kreklow et al., 2019). The relief is moderate, at 200 - 300 m over 2 - 3 km scale wavelengths. The  
570 zircons' source is a kimberlitic diatreme (Schmidt et al., 2013; Modalek et al., 2009) that intruded into  
571 Palaeozoic slates  $71.2 \pm 0.8$  Myr ago (U-Pb age; Table 2). The diatreme acts as the headwaters of the  
572 drainage system investigated. The zircons from the Vogtland form a cluster ( $n = 13$ ; Fig. 7) that is  
573 commensurate with a long (1 to 3 Myr) exposure at or near the surface, or exhumation at a very low rate  
574 ( $< 0.1 \text{ m Myr}^{-1}$ ), followed by a period of burial for 600 to 900 kyr and a recent re-emergence in the  
575 active fluvial system. Samples collected further from the source (15 vs. 5 km) appear to have longer  
576 burial histories (Fig. 7). The extremely low erosion rates inferred for exposure prior to burial ( $< 0.1 \text{ m}$   
577  $\text{Myr}^{-1}$ ) are unprecedented for temperate regions in Europe and late Quaternary erosion rates of similar  
578 moderate relief landscapes are two orders of magnitude faster ( $> 10 \text{ m Myr}^{-1}$ ; (Schaller et al., 2001)).

579

580 The termination of the initial, long exposure of the Vogtland zircons  $\sim 900$  kyr ago, coincides with the  
581 marked climatic shifts associated with the '0.9 Ma event' (Marine Isotope Stage 22 (MIS 22); (Head and  
582 Gibbard, 2015; McClymont et al., 2013; Lisiecki and Raymo, 2005)) during the Mid Pleistocene  
583 Transition (MPT)(Clark et al., 2006; Head and Gibbard, 2005; McClymont et al., 2013). In Europe this  
584 climatic shift is associated with pronounced acceleration of river incision (Gibbard and Lewin, 2009), in

585 part driven by increased sediment loads from periglacial hillslope processes (Gibbard and Lewin, 2009;  
586 Goodfellow and Boelhouwers, 2013). Until the Pleistocene, low-relief landscapes dominated throughout  
587 Europe (Gibbard and Lewin, 2009; Muttoni et al., 2003; Haeuselmann et al., 2007). This stasis came to  
588 an end during the MPT (Gibbard and Lewin, 2009; Muttoni et al., 2003; Haeuselmann et al., 2007), with  
589 a step change during MIS 22 (Gibbard and Lewin, 2009; Muttoni et al., 2003). The following, first  
590 major glaciation was MIS 16 (676 to 621 kyr; (Lisiecki and Raymo, 2005; Ehlers and Gibbard, 2007)),  
591 which overlaps with the youngest burial ages of zircons in the cluster (Fig. 7). One zircon from this  
592 group may record a shorter burial, or significant post-burial production at a shallower depth.

593

594 From the external constraints on climate and landscape evolution in Europe (Gibbard and Lewin, 2009;  
595 Head and Gibbard, 2015; McClymont et al., 2013; Pena and Goldstein, 2014) and our results (Fig. 7) we  
596 assemble the following, preliminary, scenario. A formerly stable Plio-Pleistocene landscape (Gibbard  
597 and Lewin, 2009) is exposed for the first time to periglacial conditions during MIS 22 (Head and  
598 Gibbard, 2015; Pena and Goldstein, 2014). A functional vegetation cover is largely lost and periglacial  
599 hillslope processes accelerate sediment supply (Gibbard and Lewin, 2009; Goodfellow and  
600 Boelhouwers, 2013). The ensuing surge in sediment supply may have overwhelmed the transport  
601 capabilities of low-order catchments and consequently sediments are stored on hillslopes or in the  
602 fluvial system. In the studied case, slopes would begin to be stripped of their pre-existing regolith cover  
603 during MIS 22 and this would have been largely concluded by the end of MIS 16. The finding that the  
604 burial ages of the zircons seem to increase with distance from their source locations points to a long-  
605 term burial in fluvial sediments, rather than in colluvium proximal to their source. Analyses of  
606 additional material and locations are currently ongoing to test this preliminary scenario. For the purpose  
607 of this study, we note that  $Kr_{it}$  is suitable to illuminate (Mid-) Pleistocene histories of burial and  
608 exposure.

609

## 610 **5 Discussion**

611 Our results from the suite of zircon samples taken from near-surface sediments and bedrock demonstrate  
612 the feasibility and utility of  $Kr_{it}$  for Earth surface science applications. Not all Kr isotopes are equally  
613 suitable for this purpose and some aspects concerning the main target mineral, zircon, need  
614 consideration. In the following, we elucidate these topics, outline the required research to address  
615 current limitations and explore the potential of this novel tool for Earth surface sciences.

616

### 617 **5.1 The utility of Kr-isotopes for cosmogenic applications**

618 The utility for each of the various  $Kr_{it}$  isotopes is set by its relative abundance, the presence or absence  
619 of alternative production pathways (fissionogenic and/or nucleogenic), its half-life (where applicable) and  
620 its atmospheric abundance ( $^{80}Kr$  2.25%;  $^{82}Kr$  11.6%;  $^{83}Kr$  11.5%;  $^{84}Kr$  57.0%;  $^{86}Kr$  17.3%;  $^{78}Kr$  0.35%;

621  $^{81}\text{Kr}$  0.5 ppt; (Buizert et al., 2014; Aregbe et al., 1996)), i.e., its ubiquitous general background.  
622 Specifically:  
623  
624 a)  $^{78}\text{Kr}$  and  $^{81}\text{Kr}$  are exclusively produced by cosmic rays, not by fission or nucleogenic reactions and  
625 they are the rarest Kr-isotopes in air (0.35% and 0.5 ppt in air; Fig. 1; (Buizert et al., 2014; Aregbe et al.,  
626 1996). These factors facilitate the detection and quantification of small amounts of  $\text{Kr}_{\text{it}}$ .  
627 b)  $^{80}\text{Kr}$  and  $^{82}\text{Kr}$  may be produced by nucleonic reactions on Bromine,  $^{79}\text{Br}(n, \gamma)^{80}\text{Kr}$ ,  $^{81}\text{Br}(n, \gamma)^{82}\text{Kr}$ .  
628 Reaction cross sections for thermal neutrons are 10.32 and 2.36 barn, respectively (Soppera et al.,  
629 2014). Bromine concentrations are low in silicate minerals (Ruzie-Hamilton et al., 2016; Kendrick,  
630 2012; Teiber et al., 2015) but often not constrained. The fissionogenic production of  $^{82}\text{Kr}$  is negligible  
631 (Fig. 1; (Jaea)). The presence of  $\text{Kr}_{\text{nuc}}$  can be verified and affected samples can be excluded from further  
632 interpretation (Fig. 6).  
633 c)  $^{83}\text{Kr}$ , which in meteorite studies is used as the most prominent  $\text{Kr}_{\text{fiet}}$  isotope, may be produced by  
634 fission of  $^{238}\text{U}$  (Fig. 1; (Eikenberg et al., 1993; Honda et al., 2004; Jaea)). Fissionogenic  $^{83}\text{Kr}$  in zircon can  
635 be appreciable, since zircon is commonly enriched in uranium (particularly in comparison with  
636 meteorites) and  $\text{Kr}_{\text{fis}}$  will accumulate over the geological age of zircons (Eikenberg et al., 1993; Honda  
637 et al., 2004). Consequently,  $^{83}\text{Kr}_{\text{it}}$  may not be quantified or used with the same ease as in meteorite  
638 studies.  
639 d) Spallogenic production of  $^{84}\text{Kr}$  and  $^{86}\text{Kr}$  is (very) low compared to the other isotopes (Fig. 1; Gilabert  
640 et al., 2002) and their fissionogenic production rates are highest (Fig. 1; Eikenberg et al., 1993; Jaea),  
641 limiting their utility as cosmogenic nuclides.  
642 e) Finally, the very short half-life of  $^{85}\text{Kr}$  ( $T_{1/2}=10.7$  yr; Lerner, 1963) renders this isotope less suited to  
643 Earth surface science applications, though there may be interesting applications that could benefit from  
644 this. However, concentrations of  $^{85}\text{Kr}_{\text{it}}$  will be fiendishly low, as it approaches saturation in as little as  
645 ~50 years.  
646  
647 From the above (a to e) it follows that  $^{78}\text{Kr}_{\text{it}}$ ,  $^{80}\text{Kr}_{\text{it}}$ ,  $^{81}\text{Kr}_{\text{it}}$  and  $^{82}\text{Kr}_{\text{it}}$  are probably the most useful  $\text{Kr}_{\text{it}}$   
648 isotopes for Earth surface science applications. Having three stable isotopes allows the separation of  
649 atmospheric, nucleogenic and fractionated components from cosmogenic Kr (Fig. 6). Fissionogenic  
650 production can be neglected ( $^{82}\text{Kr}$ ) or excluded ( $^{78,80,81}\text{Kr}$ ) for all four nuclides (Fig. 1). Finally,  $^{81}\text{Kr}_{\text{it}}$  has  
651 no interference by any geochemical component (Fig. 1) and has a rather useful half-life ( $T_{1/2}=229\pm 11$   
652 kyr; (Baglin, 2008)) for Earth surface science applications (Fig. 7).  
653  
654  $\text{Kr}_{\text{it}}$  is unique amongst the cosmogenic nuclides in that it has one long-lived radioactive ( $^{81}\text{Kr}$ ) and  
655 several suitable stable isotopes (Gilabert et al., 2002; Marti, 1967). As heavy residues of their target  
656 nuclei,  $\text{Kr}_{\text{it}}$  isotopes are not ejected from the target mineral, nor are they implanted from surrounding

657 material, as is the case for cosmogenic  $^3\text{He}$  (Dunai, 2010; Dunai et al., 2007; Larsen et al., 2019).  $^{78}\text{Kr}_{\text{it}}$   
658 is the only stable cosmogenic nuclide that cannot be produced by processes other than cosmogenic  
659 production during the geological life-time of a rock, as its geochemical sources are gases of atmospheric  
660 composition, unaltered since the accretion of Earth (Trieloff et al., 2000). The absence of significant  
661 muogenic pathways of Kr-production from Zr-isotopes (see Sect. 1.2.2) help facilitate its use in Earth  
662 science applications.

663

## 664 **5.2 Zircon as target mineral**

665 Zircon is ubiquitous in igneous rocks and clastic sediments, occurring in granites as well as basalts  
666 (Grimes et al., 2007; Samson et al., 2018; Keller et al., 2017). Zircon abundance in igneous rocks is  
667 usually limited by the availability of zirconium, which has an average concentration of 82 ppm in the  
668 oceanic crust (Jenner and O'Neill, 2012) and of 193 ppm in the continental crust (Taylor and McLennan,  
669 1985). Taking 193 ppm Zr as a guide, the average continental crust may contain 390 ppm zircon. While  
670 many granitoid rocks have zirconium/zircon concentrations close to the continental average, some might  
671 deviate significantly (Keller et al., 2017). Zircon is amongst the most weathering-resistant minerals and  
672 can survive the weathering-erosion-sedimentation-metamorphism-melting cycle of rocks (Hoskin and  
673 Schaltegger, 2003; Belousova et al., 2002).

674

675 Zircon ( $\text{ZrSiO}_4$ ) forms a continuous mixture series with hafnon ( $\text{HfSiO}_4$ ). In most rocks, however, the  
676 range in Hf-concentrations actually observed in zircon is small:  $1.5 \pm 1$  wt % (Hoskin and Schaltegger,  
677 2003; Belousova et al., 2002; Owen, 1987). Only highly evolved rocks, such as pegmatites, syenites or  
678 carbonatites, may show significantly higher Hf-concentrations (Hoskin and Schaltegger, 2003;  
679 Belousova et al., 2002). Since Hf does not contribute to  $\text{Kr}_{\text{it}}$ -production, its role in the target chemistry  
680 would need consideration (Hf 'dilutes' the Zr) when interpreting  $\text{Kr}_{\text{it}}$ - concentrations in zircons from  
681 such evolved rocks. Combined, all other impurities in zircon are well below the %-level (Hoskin and  
682 Schaltegger, 2003; Belousova et al., 2002), thus need no consideration when interpreting  $\text{Kr}_{\text{it}}$ -  
683 concentrations. Hence, in most geological contexts where zircon might be used for cosmogenic  
684 methodology, a composition of  $98.5 \pm 1$  %  $\text{ZrSiO}_4$  may safely be assumed (Hoskin and Schaltegger,  
685 2003; Belousova et al., 2002; Owen, 1987), without performing a chemical assay.

686

687 Retention of noble gases in zircon is very good (Honda et al., 2004; Farley, 2007). The closure  
688 temperature for Kr is between 500 and 600°C (Honda et al., 2004). This may be a mixed blessing for  
689 some applications of  $\text{Kr}_{\text{it}}$ . On one hand, the excellent retentivity makes paleo-erosion rate studies in  
690 diagenetically altered to slightly metamorphosed rocks feasible. On the other hand, potentially  
691 incomplete resetting of the (stable)  $\text{Kr}_{\text{it}}$  by thermal diffusion in source rocks might complicate  
692 applications such as burial dating (Dunai, 2010). In any case, the retentivity of  $\text{Kr}_{\text{it}}$  under environmental

693 conditions will be complete in structurally intact zircons. The qualifier ‘structurally intact’ is pointing to  
694 the fact that radioactivity within the zircon ( $\alpha$ -decay of U, Th, Sm) causes cumulative radiation damage  
695 over time. This can eventually lead to complete destruction of the lattice and amorphization of the  
696 material (metamictization; (Ewing et al., 2003)). This process goes hand-in-hand with an increase in  
697 volume (lowering of density by up to 17%; (Ewing et al., 2003)). Evidence from other noble gases  
698 (Guenther et al., 2013) and other minerals (Eikenberg et al., 1993; Ragettli et al., 1994) suggests that  
699 the retentivity of  $Kr_{it}$  may be an issue for highly metamict zircons. The glassy nature of highly metamict  
700 zircons also renders them more vulnerable to weathering (Ewing et al., 2011). However, it still takes  
701 intense tropical weathering (laterization) to (partially) destroy metamict zircons (Delattre et al., 2007).

702

### 703 **5.3 Applications in the Earth sciences**

704 Zircon as a target material stands out in terms of weathering resistance (Hoskin and Schaltegger, 2003;  
705 Belousova et al., 2002) and retentivity for noble gases (Honda et al., 2004; Farley, 2007). This  
706 combination of characteristics complements existing cosmogenic nuclide methodology (Dunai, 2010;  
707 Marti, 1967; Granger and Riebe, 2014; Gosse and Phillips, 2001). For instance, basin-wide denudation  
708 rates (Granger and Riebe, 2014) of lateritic regoliths, which cover large tracts of the Earth surface (e.g.,  
709 (Burke et al., 2008)), and quartz-free lithologies such as basalts, which are important for  $CO_2$  draw-  
710 down (Dessert et al., 2003), may be reliably addressed without the bias that is introduced when target  
711 minerals perish during weathering (Granger and Riebe, 2014). The additional information obtained by  
712 combining cosmogenic nuclides with different half-lives is inherently available, as the relevant  $Kr_{it}$   
713 isotopes are measured simultaneously. The important detail that  $^{78}Kr$  has no other sources than gases of  
714 atmospheric composition and cosmogenic production, allows, in principle, the determination of paleo-  
715 erosion rates from clastic sedimentary rocks of all ages.

716

717 The results presented here provide an idea of the utility of this new tool for dating changes of process  
718 rates on the Earth surface (MPT in temperate regions), or testing their notional long-term invariance  
719 (African Surface). The ability to use stable/radionuclide pairs to track the exposure and burial history of  
720 single grains of coarse sand or fine gravel helps to achieve this. However, amalgamated, multi-grain  
721 samples for  $Kr_{it}$  are also possible and allow averaging approaches as are routinely available for other  
722 cosmogenic nuclides (Granger and Riebe, 2014), with the added benefits of an inherent  
723 stable/radionuclide pair and the unique weathering properties of zircon.

724

### 725 **6 Conclusions**

726 From this first study of in situ produced terrestrial krypton ( $Kr_{it}$ ) we draw the following conclusions.

- 727 1. In situ produced cosmogenic krypton in terrestrial zircon can be analysed with the existing sector  
728 field mass spectrometry methodology. A high-resolution mass spectrometer aids resolving

- 729 interferences from hydrocarbons and  $\text{Ar}_2\text{H}^+$ . Likewise, a low-blank laser-extraction of Kr from  
730 zircon aids resolving small isotopic enrichments relative to atmospheric Kr.
- 731 2.  $^{78}\text{Kr}$ ,  $^{80}\text{Kr}$ ,  $^{81}\text{Kr}$  and  $^{82}\text{Kr}$  are the most suitable Kr-isotopes for terrestrial applications; this  
732 judgement is based on their abundance in air, the half-life of  $^{81}\text{Kr}$  and the absence, or rarity of  
733 interfering geochemical components.
- 734 3. Cross-calibration to  $^{10}\text{Be}$ -production in quartz ( $^{81}\text{Kr}_{\text{it}}(\text{zrc})/^{10}\text{Be}(\text{qtz})=1.545\pm 0.045$ ) yields a  
735 production rate of  $^{81}\text{Kr}_{\text{it}}$  in zircon of  $6.33\pm 0.32$  atoms  $\text{g}^{-1} \text{yr}^{-1}$  at sea-level and high-latitude. Our  
736 measurements indicate a terrestrial  $^{81}\text{Kr}/^{78}\text{Kr}_{\text{it}}$  production ratio in zircon of  $1.94\pm 0.09$  and that the  
737 air-spallogenic mixing line in  $^{78}\text{Kr}/^{82}\text{Kr}$ - $^{80}\text{Kr}/^{82}\text{Kr}$  space (Fig. 6) has a slope of  $1.682\pm 0.015$   
738 (uncertainties are 1SD).
- 739 4. As heavy residues of spallation,  $\text{Kr}_{\text{it}}$ -nuclei are neither implanted into zircon nor ejected from  
740 zircon. Hence,  $\text{Kr}_{\text{it}}$  production rates are not dependent on grain-size or matrix, as is the case for  
741 cosmogenic  $^3\text{He}$  (Dunai, 2010; Larsen et al., 2019).
- 742 5. Interfering geochemical components and physical processes (fractionation) can be reliably  
743 identified using  $^{78}\text{Kr}$ ,  $^{80}\text{Kr}$  and  $^{82}\text{Kr}$ ; similar to the existing methodology for cosmogenic neon  
744 (three-isotope diagram; Niedermann, 2002).
- 745 6. The combination of a stable  $\text{Kr}_{\text{it}}$ -isotope (here  $^{78}\text{Kr}_{\text{it}}$ ) and radioactive  $^{81}\text{Kr}_{\text{it}}$  ( $T_{1/2} = 229$  kyr, Baglin,  
746 2008) allows the reconstruction of complex histories of exposure and burial, similar to the existing  
747 methodology for  $^{10}\text{Be}$  and  $^{26}\text{Al}$  ('banana plot'; Lal, 1991). The shorter half-life of  $^{81}\text{Kr}$ , as compared  
748 to  $^{26}\text{Al}$  ( $T_{1/2} = 708$  kyr, Nishiizumi, 2004) permits reconstructions of younger burial histories, as  
749 compared to existing methodology (i.e., combining  $^{10}\text{Be}$  and  $^{26}\text{Al}$  and assuming similar analytical  
750 uncertainties for equivalent exposure). The upper time-limit for resolving burial histories should be  
751 lower than 2 Myr, with the actual values of the upper and lower limits dependent on the analytical  
752 uncertainties.
- 753 7. In situations with a long, continuous exposure ( $> 1$  Ma),  $^{81}\text{Kr}$ -Kr-ages, which are independent of  
754 scaling, may be calculated using the existing methodology from meteoritics (Marti, 1967; Leya et  
755 al., 2015).
- 756 8.  $^{78}\text{Kr}$  has no sources other than gases of atmospheric composition and cosmogenic production,  
757 allowing, in principle, the determination of paleo-erosion rates from clastic sedimentary rocks of all  
758 ages.
- 759  
760

761 **Author contribution**

762 TJD conceptualized the study and designed the noble gas experiments. Investigation and formal  
763 analysis of data was carried out by all authors. TJD prepared the manuscript with contributions  
764 from all co-authors.

765

766 **Competing interests:**

767 The authors declare that they have no conflict of interest.

768

769 **Acknowledgements**

770 TJD would like to thank Sven Kreher (Goldmuseum Buchwald) for providing the zircons from  
771 the Vogtland, sharing detailed information on the sampling sites and hands-on experience with  
772 washing zircons. Many thanks to Georgina King and Peter Abbott for collecting and  
773 documenting sample GRIM-1. The safe execution of the high-temperature extractions was  
774 enabled by Andreas Vogt. TJD owes the integrity of the laser extraction line and probably his  
775 health to these efforts, and would like to express his special thanks. TJD is very grateful to  
776 Andreas Knecht (PSI) for pointing out errors in initial estimates of muon reaction probabilities.
