Abstract. *In situ* carbonate U-Pb dating studies have proliferated dramatically in recent years. Almost all these studies have targeted relatively young calcite up to Carboniferous in age. To assess the robustness of the carbonate U-Pb chronometer in deep-time, we carried out *in situ* U-Pb analyses in magnesite-ankerite-calcite carbonates in the martian meteorite Allan Hills (ALH) 84001. Carbonates in ALH 84001 formed at *ca.* 3.94 Ga, and there is little evidence that much happened to this rock since then, making it an ideal sample to test the robustness of the U-Pb system in old carbonates. We obtained a concordant date of $3941 \pm 49/110$ Ma ($n = 14$, MSWD = 2.0), which is identical to the step-leaching Rb/Sr date determined previously. These results thus confirm that old carbonates are amenable to U-Pb dating in samples that have had a relatively simple history post-carbonate formation.

1 Introduction

15 Analytical developments in laser ablation – inductively coupled plasma mass spectrometry (LA-ICP-MS) over the last decade have driven important progress in *in situ* dating of carbonates, and in particular of calcite and occasionally dolomite, using the radioactive decay of uranium (U) into lead (Pb) (see the recent review by Roberts *et al.*, 2020, for example). Indeed, biogenic, diagenetic, and vein carbonates can typically incorporate up to *ca.* 10-20 $\mu\text{g.g}^{-1}$ U, and up to *ca.* 100 $\mu\text{g.g}^{-1}$ U in speleothems (e.g., Roberts *et al.*, 2020). Carbonates also incorporate initial Pb, meaning that multiple analyses on carbonate samples often
20 yield linear arrays in a Tera-Wasserburg inverse concordia diagram, providing information on both the $^{207}\text{Pb}/^{206}\text{Pb}$ composition of the initial Pb and the age of formation of the carbonates. Recent applications of carbonate U-Pb dating using LA-ICP-MS include constraining the timing of sedimentation, lithification, and diagenesis (e.g., Drost *et al.*, 2018; Godeau *et al.*, 2018; Mueller *et al.*, 2020; Brigaud *et al.*, 2021), faulting (e.g., Ring and Gerdes, 2016; Roberts and Walker, 2016; Goodfellow *et al.*, 2017; Nuriel *et al.*, 2017; 2019; Hansman *et al.*, 2018; Beaudoin *et al.*, 2018; Holdsworth *et al.*, 2019; Smeraglia *et al.*,
25 2019), aragonite to calcite conversion in ammonites (Li *et al.*, 2014), alteration of oceanic crust (Coogan *et al.*, 2016), veining, hydrothermalism, and mineralisation (Burisch *et al.*, 2017; 2018; Parrish *et al.*, 2018; Walter *et al.*, 2018; Bertok *et al.*, 2019; Drake *et al.*, 2019; 2020; MacDonald *et al.*, 2019), palaeoclimate reconstructions (Nicholson *et al.*, 2020), and hominin dispersion (Scardia *et al.*, 2019), for example.

30 All these *in situ* studies have targeted relatively young samples (younger than *ca.* 465 Ma), with two-third of dates younger
than 50 Ma, and all but two younger than 300 Ma (Supplementary Table S1). This is consistent with the accepted idea that
carbonates are not very resistant to resetting of their U-Pb isotope systematics when thermal- and/or fluid-related alteration
events take place after their formation (e.g., Roberts *et al.*, 2020). However, a few studies have focused on dating older
carbonate samples, using wet chemistry to isolate Pb isotopes, and obtained Pb/Pb isochron dates ranging between *ca.* 1.60
35 and 2.84 Ga (Moorbath *et al.*, 1987; Bau *et al.*, 1999; Ray *et al.*, 2003; Sarangi *et al.*, 2004; Farey *et al.*, 2013). These Pb/Pb
dates have been interpreted as dating the deposition of these carbonates, suggesting that in some settings the Pb isotope
systematics of carbonates can remain undisturbed for billions of years. To further assess the robustness of the carbonate U-Pb
chronometer in deep time, we decided to attempt *in situ* LA-ICP-MS U-Pb dating of carbonates in the martian meteorite Allan
Hills 84001 (ALH 84001). The formation of these carbonates has been dated at 3.94 ± 0.02 Ga (2σ) using Rb-Sr analyses on
40 acid leachates via thermal ionisation mass spectrometry (Borg *et al.*, 1999; Beard *et al.*, 2013; date recalculated using a ^{87}Rb
decay constant of $1.3972 \times 10^{-11} \text{ yr}^{-1}$; Villa *et al.*, 2015).

The meteorite ALH 84001 is an orthopyroxenite, a cumulate rock mostly comprising orthopyroxene, olivine, and chromite
(e.g., Mittlefehldt, 1994), which formed *ca.* 4.1 Ga ago as suggested by Lu-Hf and Pb/Pb dating (Bouvier *et al.*, 2009; Lapen
45 *et al.*, 2010). Carbonate-rich areas are irregularly scattered throughout ALH 84001, appearing as spherical or hemispherical
globules, discs along fractures, and irregular fillings in orthopyroxene (see review by Treiman (2021), and references therein).
The patches of carbonates show strong compositional zoning ranging from calcite-rich to magnesite-siderite solid solution
compositions (e.g., Corrigan and Harvey, 2004; Holland *et al.*, 2005). These carbonates likely formed at low temperature (*ca.*
10–20 °C; Halevy *et al.*, 2011; del Real *et al.*, 2016) during fluid-rock interactions that were broadly contemporaneous with
50 the main shock event recorded in ALH 84001 (e.g., Treiman, 2021). Dating carbonate-rich fractions using the Rb-Sr system
yielded a precise formation age of 3.94 ± 0.02 Ga (2σ ; Borg *et al.*, 1999; Beard *et al.*, 2013), which is consistent with a less
precise Pb/Pb isochron corresponding to a date of 4.045 ± 0.090 Ga (2σ ; Borg *et al.*, 1999). As stated by Treiman (2021),
“*there is little evidence that anything had happened to ALH 84001 since 3.9 Ga*” and the time of carbonate formation until it
was launched from Mars *ca.* 14 Ma ago (Eugster *et al.*, 1997), which is crucial with respect to the U-Pb system having remained
55 closed since ALH 84001 carbonates formed.

2 Studied sample

The studied polished section (Fig. 1) was derived from a chip of the ALH84001,287 allocation from the NASA Ancient Mars
Meteorite Program. The section contains patches of carbonates, associated with chromite, in between larger orthopyroxene
grains (Fig. 1). The carbonates display the range of compositions typical for ALH 84001 carbonates, from Mg-rich magnesite
60 to Ca-rich calcite, with intermediate Fe-rich ankerite areas (Fig. 1). The Mg- and Fe-rich carbonates seem to be part of broken
rosettes, while Ca-rich carbonates appear associated with maskelynite (Fig. 1).

3 Laser Ablation – Inductively Coupled Plasma Mass Spectrometer analyses

U-Pb analyses were carried out at the University of Manchester using a Teledyne Photon Machines Analyte Excite+ 193 nm
65 ArF excimer laser ablation system equipped with a HelEx II active 2-volume ablation cell, coupled to an Agilent 8900 triple
quadrupole Inductively Coupled Plasma Mass Spectrometer (ICP-MS) using a signal-smoothing device (see Supplementary
Table S2) for a summary of the analytical setup and data processing procedure).

The material ablated from target carbonates was carried to the ICP-MS by high purity He, which was mixed with Ar before
70 injection into the plasma source. High purity N₂ was added to the He stream at a flow rate of 2 mL.min⁻¹ to enhance
sensitivity. Tuning of the ICP-MS and mass calibration were performed at the start of the analytical session by optimising
the ion signals during ablation of the NIST SRM 612 reference glass, while maintaining ²³⁸U⁺/²³²Th⁺ close to unity and
minimising the ²³²Th¹⁶O⁺/²³²Th⁺ ratio (*ca.* 0.3%). Glass and carbonates were ablated using a 25 μm laser beam size, a fluence
of 4 J.cm⁻², and a repetition rate of 5 Hz. Each analyses lasted 50 s and was preceded by 30 s counting time of the gas blank
75 (background). The masses analysed and corresponding dwell times are reported in Supplementary Table S2.

The reference glass NIST614 (0.823 μg.g⁻¹ U, 2.32 μg.g⁻¹ Pb; Jochum *et al.*, 2011) was used to correct for ²⁰⁷Pb/²⁰⁶Pb
fractionation, while mass bias correction of the measured ²³⁸U/²⁰⁶Pb ratios was carried out using repeated analyses of the
reference calcite WC-1, which has a thermal ionisation mass spectrometry (TIMS) age of 254.4 ± 6.4 Ma (Roberts *et al.*,
80 2017). To ensure accuracy, the Duff Brown Tank (DBT) calcite (64.0 ± 0.7 Ma; Hill *et al.*, 2016) and AUG-B6 calcite (43.0
± 1.0 Ma; Pagel *et al.*, 2018) were also analysed and used as secondary reference materials.

Data processing was carried out using Iolite v4.5, using the NIST614 glass as primary reference material to remove
instrument baseline contributions, mass bias of Pb isotopes, and downhole fractionation and instrumental drift of ²⁰⁶Pb/²³⁸U
85 ratios (Paton *et al.*, 2011). The reproducibility obtained on NIST614 for ²⁰⁷Pb/²⁰⁶Pb (±1.7%, *n* = 9, 95% confidence level)
and ²⁰⁶Pb/²³⁸U (±1.6%, *n* = 9, 95% confidence level) ratios were propagated by quadrature addition into each analysis
²⁰⁷Pb/²⁰⁶Pb and ²⁰⁶Pb/²³⁸U individual uncertainties. Repeated analyses of the NIST612 glass yielded an average ²⁰⁷Pb/²⁰⁶Pb
ratio of 0.871 ± 0.044 (*n* = 8, 2 standard deviation), which is within error of its known ²⁰⁷Pb/²⁰⁶Pb ratio of 0.90745 ± 0.00004
(Baker *et al.*, 2004).

90

The data obtained for the reference calcite WC-1 were then plotted in a Tera-Wasserburg diagram using IsoplotR
(Vermeesch, 2018), and yielded a lower intercept uncorrected date of 255.2 ± 5.9 Ma (95% confidence level, MSWD = 1.1,
n = 10) for a discordia anchored at a common ²⁰⁷Pb/²⁰⁶Pb ratio of 0.85 (Roberts *et al.*, 2017). To obtain the known intercept
age of 254.4 ± 6.4 Ma for the WC-1 calcite, we applied a linear correction factor of 1.0031 to the ²⁰⁶Pb/²³⁸U ratios, which we
95 also applied to all the samples analysed in the session. All calculated dates are associated with two uncertainties, the first one

including the random uncertainties for each analysis (internal uncertainties on measured $^{207}\text{Pb}/^{206}\text{Pb}$ and $^{206}\text{Pb}/^{238}\text{U}$ ratios and reproducibility on repeated NIST614 analyses), while systematic uncertainties (2.5% uncertainty on the WC-1 age, and 0.14% and 0.11% on the ^{235}U and ^{238}U decay constants, respectively; Jaffey *et al.*, 1971) are propagated by quadratic addition in the second one.

100

The data obtained on the DBT calcite yielded a lower intercept date of $64.9 \pm 2.2/2.8$ Ma (95% confidence level, MSWD = 2.9, $n = 12$) for a discordia anchored at a common $^{207}\text{Pb}/^{206}\text{Pb}$ ratio of 0.74 (Hill *et al.*, 2016) (Supplementary Fig. S1).

Because of its lower U abundance and younger age, the data obtained on the AUG-B6 calcite are less precise, yielding a concordia date of $40.8 \pm 2.0/2.2$ Ma (95% confidence level, MSWD concordance + equivalence = 2.2, $n = 8$)

105 (Supplementary Fig. S1), which is consistent with a $^{238}\text{U}/^{206}\text{Pb}$ weighted average date of $41.6 \pm 2.1/2.3$ Ma (95% confidence level, MSWD = 0.4, $n = 8$). All results are available in Supplementary Table S3.

4 Results

The carbonates analysed in ALH 84001 contain *ca.* 0.1-0.4 $\mu\text{g}\cdot\text{g}^{-1}$ U and 0.1-0.5 $\mu\text{g}\cdot\text{g}^{-1}$ Th (Table 1). When plotted in a Tera-Wasserburg $^{207}\text{Pb}/^{206}\text{Pb}$ vs. $^{238}\text{U}/^{206}\text{Pb}$ diagram, ALH 84001 carbonates yield a concordant date of $3941 \pm 49/110$ Ma ($n = 14$,
110 MSWD = 2.0; Fig. 2A), which is identical to a weighted mean $^{207}\text{Pb}/^{206}\text{Pb}$ date of $3967 \pm 56/113$ Ma ($n = 14$, MSWD = 1.9; Fig. 2B). Carbonate analyses plot on the concordia curve, indicating that they do not contain appreciable amount of common Pb. This is consistent with the measured ^{204}Pb intensities that are within error of 0 counts per second (Table 1).

5 Discussion and implications

5.1 Comparison with previous ALH 84001 carbonate dating studies

115 *In situ* U-Pb dating of carbonates in ALH 84001 using LA-ICP-MS yields a concordia date of $3941 \pm 49/110$ Ma, which is identical to the carbonate step-leaching Rb-Sr isochron date of 3.94 ± 0.02 Ga (Borg *et al.*, 1999; Beard *et al.*, 2013) and the less precise Pb/Pb isochron date of 4.045 ± 0.090 Ga (Borg *et al.*, 1999). Before propagating the $\pm 2.5\%$ uncertainty associated with the age of the primary U-Pb reference carbonate WC-1, and the uncertainties associated with the ^{238}U and ^{235}U decay constants, the carbonate U-Pb concordia date is accompanied with a fairly precise 2σ uncertainty of $\pm 1.2\%$, which increases
120 to $\pm 2.8\%$ when all uncertainties are propagated. This suggests that *in situ* U-Pb dating of carbonates has the potential to yield precise dates, but also highlights the need to reduce uncertainties on reference materials. Our LA-ICP-MS results also indicate that using a calcite primary reference material for correcting U/Pb fractionation in Mg- and Fe-rich carbonate matrices, such as magnesite and ankerite, produce accurate dates (within the obtained uncertainties). A final point worth highlighting is the fact that carbonates in ALH 84001 do not contain appreciable amount of common Pb, as indicated by their concordant U-Pb
125 date of *ca.* 3.94 Ga and their ^{204}Pb intensities within error of 0 count per second. This is unusual, as in most examples in

terrestrial systems carbonates, do contain common Pb incorporated during their crystallisation (e.g., Roberts *et al.*, 2020). This observation suggests that the fluids from which ALH 84001 carbonates formed contained very little Pb.

5.2 Robustness of the carbonate U-Pb chronometer and further applications

Our *in situ* LA-ICP-MS analyses confirm that carbonates in ALH 84001 formed *ca.* 3.94 Gyr-ago, and that the U-Pb
130 chronometer in these carbonates has remained closed to any disturbance event since they formed. This is consistent with the
suggestion that not much happened to ALH 84001 between 3.9 Ga and its launch from Mars 14 Myr-ago (Treiman, 2021), and
indicates that this latter event did not reset the carbonate U-Pb chronometer. Carbonates in terrestrial Archean samples are
probably not the best suited for U-Pb dating as most Archean formations would have been heated up to at least low greenschist
135 metamorphic conditions and/or been affected by hydrothermal alteration, because the Earth is geologically active and harbours
a complex hydrological cycle. On the other hand, results of this study open up opportunities for dating old carbonates in
samples that have had a relatively simple history post-carbonate formation. For example, volatile-rich carbonaceous chondrites
(e.g., CI and CM chondrites) typically contain carbonates formed during fluid-rock interactions on their parent-asteroids *ca.*
4563-4561 Myr-ago (e.g., Jilly-Rehak *et al.*, 2017, and references therein), which is within 10 Myr of the formation of the first
140 solids in the Solar System. After this phase of early hydrothermal alteration, it is thought that not much happens to these
samples on their parent asteroids until they end up on the Earth as meteorite fragments. Carbonates in carbonaceous chondrites
could thus be prime targets to further constrain the timing of hydrothermal alteration on volatile-rich asteroids using the U-Pb
dating chronometer.

Data availability

Raw LA-ICP-MS data and metadata are provided in Supplementary Material.

145 Author contribution

ICL acquired and prepared the sample. RT designed the experiment, performed the analysis, and interpreted the results. RT prepared the manuscript with contributions from ICL.

Competing interests

The authors declare that they have no conflict of interest.

150 Acknowledgments

We acknowledge the provision of the sample of ALH84001 from the NASA Ancient Mars Meteorite Programme, and funding from STFC (#ST/P005225/1 to RT), and The University of Manchester and STFC (grant #ST/S002170/1) for funding the LA-

ICP-MS facility. Many thanks to Nick Roberts for providing us with the WC-1 calcite, Benjamin Brigaud and Thomas Blaise for the AUG-B6 calcite, and Victor Polyak for the Duff Brown Tank calcite.
